Abstract

This paper presents a nonlinear deterministic model for assessing the impact of public health education campaign on curtailing the spread of the HIV pandemic in a population. Rigorous qualitative analysis of the model reveals that it exhibits the phenomenon of backward bifurcation (BB), where a stable disease-free equilibrium coexists with a stable endemic equilibrium when a certain threshold quantity, known as the *effective reproduction number* (\mathcal{R}_{eff}), is less than unity. The epidemiological implication of BB is that a public health education campaign could fail to effectively control HIV, even when the classical requirement of having the associated reproduction number less than unity is satisfied. Furthermore, an explicit threshold value is derived above which such an education campaign could lead to detrimental outcome (increase disease burden),

13 and below which it would have positive population-level impact (reduce disease
14 burden in the community). It is shown that the BB phenomenon is caused by
15 imperfect efficacy of the public health education program. The model is used to
16 assess the potential impact of some targeted public health education campaigns
17 using data from numerous countries.

19 tion.

20 **1 Introduction**

21 Since its emergence in the 1980s, the human immunodeficiency virus (HIV), and the as-
22 sociated syndrome of opportunistic infections which lead to the late stage HIV disease,
23 known as the acquired immunodeficiency syndrome (AIDS), continues to be one of the
24 most serious global public health menace. Over 33 million people are currently living
25 with HIV (UNAIDS, 2007). Based on the current trends, over 6800 persons become
26 infected with HIV, and 5700 die from AIDS-related causes, every day (UNAIDS, 2007).
27 AIDS is the leading cause of death in sub-saharan Africa, especially in the southern
28 part of the continent. Moreover, 68% of HIV-related deaths and 76% of the total new
29 infections occurred in sub-saharan Africa (UNAIDS, 2007). There is still no cure or
30 vaccine for HIV, and anti-retroviral drugs (ARVs) are still not widely accessible, partic-
31 ularly in the resource-poor nations (which suffer the vast majority of the HIV burden
32 globally). Yet, HIV remains preventable through the avoidance of high-risk behaviour,
33 such as unprotected sexual intercourse and sharing of drug injection needles. Thus,
34 in the absence of pharmaceutical interventions (such as a vaccine or ARVs) in areas
35 where the HIV pandemic is more rampant (notably developing nations), the effective
36 control of HIV would depend, primarily, on reducing behavioural risks. This could be

37 achieved through effective public health education campaign.

38 Unfortunately, however, surveys around the world show alarming low level of aware-
39 ness and understanding about HIV and its preventive measures (Keitshokil *et al.*, 2007;
40 Pérez *et al.*, 2008). Recent studies indicate that the most effective available means to
41 control the prevalence of HIV is to provide HIV-related education, which will lead to
42 safe lifestyles among sexually-active members of the public (Bortolotti *et al.*, 1992;
43 Morton *et al.*, 1996). Moreover, education, as a sole anti-HIV intervention strategy,
44 may not be sufficient to motivate behaviour change (Berker & Joseph, 1998). Studies
45 show that public health education increases self-efficacy, which is a determinant for
46 controlling risky behaviour (Lindan *et al.*, 1991). Furthermore, as noted by Cassell
47 *et al.* (2006), the benefits of new methods of HIV prevention could be jeopardised
48 if they are not accompanied by positive efforts to change risky behaviour. This is
49 in line with the well-known fact that sexual education and awareness of the risk and
50 life-threatening consequences of AIDS can lower the incidence rate in HIV infection
51 (Velesco-Hernandez & Hsieh, 1994).

52 Public health education campaigns have been successfully implemented in numerous
53 countries and communities, such as: Uganda, Thailand, Zambia and the US gay com-
54 munity (Daniel & Rand, 2003; de Walque, 2007). Between 1991-1998, HIV prevalence
55 dramatically declined in Uganda from 21% to 9.8% (with a corresponding reduction
56 in non-regular sexual partners by 65% coupled with greater levels of awareness about
57 HIV/AIDS; Daniel & Rand, 2003). The Ugandan programme fostered community
58 mobilization towards change in risky behaviour, without increasing stigma (Green *et*
59 *al.*, 2006; Wilson, 2004). In Zambia, the decline in HIV incidence since early 1990s is
60 attributed to behavioural changes (Fylkesnes, 2001).

61 There are a number of ways (or strategies) public health education campaigns can be
62 implemented (or targeted) effectively to combat the burden of HIV disease (measured

63 in terms of new cases, mortality etc) in a community. This study considers the following
64 targeted strategies:

- 65 • targeting adult (“established”) sexually-active susceptible individuals only;
- 66 • targeting newly-recruited sexually-active susceptible individuals only;
- 67 • targeting HIV-infected individuals without clinical AIDS symptoms only; or
- 68 • targeting HIV-infected individuals with AIDS symptoms only.

69 The primary goal of this study is to theoretically determine which of the aforemen-
70 tioned targeted strategies (or combination of strategies) is (are) the most effective in
71 curtailing HIV spread in a community.

72 A number of mathematical models have been designed and used to study the impact
73 of preventive control strategies on the spread of HIV/AIDS in given populations. Some
74 of these studies have shown that a change in risky behaviour is necessary to prevent
75 raging HIV/AIDS prevalence, even in the presence of a vaccine and/or treatment (see,
76 for instance, Anderson, 1988; Blower & McLean, 1994; Del Valle *et al.*, 2004; Kribs-
77 Zaleta & Valesco-Hernandez, 2000). Anderson (1988) predicts rapid transmission
78 of HIV when the infected individuals engage in risky behaviours. Smith & Blower
79 (2004) reported that disease-modifying vaccines will reduce HIV transmission if they
80 cause a reduction of 1.5 \log_{10} copies/mL or more in viral load and if risky behaviours
81 do not increase. The studies mentioned above tend to emphasize the use of pharma-
82 ceutical interventions (such as vaccine and ARVs), which are not readily and widely
83 available (especially in resource-poor nations, which constitute the vast majority of
84 the global HIV prevalence). Thus, it is instructive to study models that focus on non-
85 pharmaceutical interventions, such as the use of public health education campaign.
86 A few modelling studies, such as those by Mukandavire *et al.* (2009), Mukandavire

87 and Garira (2007) and Del Valle *et al.* (2004), have investigated the impact of public
88 health educational campaigns on the transmission dynamics of HIV/AIDS in some pop-
89 ulations. The purpose of the current study is to extend some of the aforementioned
90 studies, by designing and analyzing a new comprehensive model, for HIV transmis-
91 sion in a population, that incorporates the role of public health education campaign
92 (and using the model to evaluate the impact of some targeted public health education
93 strategies).

94 The paper is structured as follows. The model is formulated and fitted with real
95 data in Section 2. Public health education campaign strategies are assessed, both
96 theoretically and numerically, in Section 3. The existence of backward bifurcation is
97 established in Section 4.

98 **2 Model Formulation**

99 The total population at time t , denoted by $N(t)$, is sub-divided into the following mu-
100 tually exclusive sub-populations: uneducated susceptible individuals ($S_u(t)$), educated
101 susceptible individuals ($S_e(t)$), uneducated infected individuals with no AIDS symp-
102 toms ($I_u(t)$), educated infected individuals with no AIDS symptoms ($I_e(t)$), uneducated
103 infected individuals with AIDS symptoms ($A_u(t)$) and educated infected individuals
104 with AIDS ($A_e(t)$). Here, (un)educated means individuals who (do not) receive proper
105 public health education or counseling against risky practices that may result in HIV
106 infection. The model takes the form of the following deterministic system of nonlinear
107 differential equations:

$$\begin{aligned}
\frac{dS_u}{dt} &= \Pi(1-p) - \xi S_u - [\lambda_u + (1-\kappa)\lambda_e]S_u - \mu S_u, \\
\frac{dS_e}{dt} &= \Pi p + \xi S_u - (1-\epsilon)[\lambda_u + (1-\kappa)\lambda_e]S_e - \mu S_e, \\
\frac{dI_u}{dt} &= [\lambda_u + (1-\kappa)\lambda_e]S_u - \sigma_u I_u - \mu I_u - \psi_1 I_u, \\
\frac{dA_u}{dt} &= \sigma_u I_u - \psi_2 A_u - \mu A_u - \delta_u A_u, \\
\frac{dI_e}{dt} &= (1-\epsilon)[\lambda_u + (1-\kappa)\lambda_e]S_e + \psi_1 I_u - \sigma_e I_e - \mu I_e, \\
\frac{dA_e}{dt} &= \sigma_e I_e + \psi_2 A_u - \mu A_e - \delta_e A_e,
\end{aligned} \tag{1}$$

108 where,

$$\lambda_u = \frac{\beta(I_u + \eta_u A_u)}{N} \quad \text{and} \quad \lambda_e = \frac{\beta(I_e + \eta_e A_e)}{N}.$$

109 The rates λ_u and λ_e above are the *forces of infection* associated with HIV transmis-
110 sion by uneducated (at the rate λ_u) and educated (at the rate λ_e) infected individuals,
111 respectively. The parameter β is the effective contact rate (that is, contact that may
112 result in HIV infection), while the parameters $\eta_u > \eta_e > 1$ account for the relative
113 infectiousness of individuals with AIDS symptoms in comparison to the corresponding
114 infected individuals with no AIDS symptoms. Unlike in the other related modelling
115 studies, such as those by Mukandavire *et al.* (2009), Mukandavire & Garira (2007)
116 and Del Valle *et al.* (2004), this study allows for the transmission of HIV by individ-
117 uals with AIDS symptoms (in line with Elbasha & Gumel, 2006 and also Garba &
118 Gumel, 2010).

119 Recruitment into the sexually-active population occurs at a rate Π (all newly-
120 recruited individuals are assumed to be susceptible to HIV infection), and a fraction, p ,
121 of these newly-recruited sexually-active individuals are assumed to be educated about

122 the risks and consequences of the HIV disease. Uneducated susceptible individuals (ex-
 123 cluding the newly-recruited individuals) receive education about safer sex practices at
 124 a rate ξ . Susceptible people acquire infection following effective contact with infected
 125 individuals (at the rates λ_u and λ_e). It is assumed that educated infected individuals
 126 (in I_u or A_u class) modify their behaviour positively, thereby reducing their risk of
 127 HIV transmission by a factor κ , with $0 < \kappa < 1$. In other words, it is assumed that
 128 HIV-infected individuals that received public health education transmit the disease at
 129 a lower rate in comparison to uneducated HIV infected individuals. Educated sus-
 130 ceptible individuals acquire infection at a reduced rate $(1 - \epsilon)[\lambda_u + (1 - \kappa)\lambda_e]$, where
 131 $0 < \epsilon < 1$ is the efficacy of public health education in preventing new infection of
 132 educated susceptible individuals.

133 Uneducated infected individuals progress to AIDS at a rate σ_u , while educated
 134 infected individuals progress at a reduced rate $\sigma_e < \sigma_u$ (in other words, infected in-
 135 dividuals who received public health education progress to AIDS at a slower rate in
 136 comparison to those who do not). Uneducated infected individuals without AIDS
 137 symptoms (I_u) are educated at a rate ψ_1 , and move to the corresponding educated
 138 infected class (I_e). Individuals in all classes suffer natural death at a rate μ . Addi-
 139 tionally, individuals with AIDS die at a rate δ_u (for the uneducated class) or δ_e (for
 140 the educated class) such that $\delta_e < \delta_u$. Thus, it is assumed that AIDS patients who
 141 received public health education die due to AIDS at a slower rate than the AIDS pa-
 142 tients who do not. Uneducated individuals with symptoms of AIDS (A_u) are educated
 143 at a rate ψ_2 , and move to the corresponding educated class (A_e). A schematic diagram
 144 of the model is depicted in Figure 1, and the associated variables and parameters are
 145 described in Table 1.

146 The model (1) is an extension of the models by Mukandavire *et al.* (2009), Mukan-
 147 davire & Garira (2007) and Del Valle *et al.* (2004), by

- 148 (i) allowing for HIV transmission by the individuals with AIDS symptoms;
- 149 (ii) offering public health education to all infected individuals (except for the edu-
150 cation of high-risk people with AIDS in Mukandavire and Garira, 2007; public
151 health education is only restricted to susceptible individuals in Mukandavire *et*
152 *al.*, 2009; and Del Valle *et al.*, 2004);
- 153 (iii) stratifying the infected population in terms of whether or not they received public
154 health education (and those who received public health education are assumed
155 to transmit HIV at a lower rate, as well as progress to AIDS and die at a slower
156 rate, in comparison to those who do not receive public health education).
- 157 (iv) The model extends the model by Garba & Gumel, 2010 by including a class of
158 susceptible individuals who receive public health education, educating a fraction
159 of newly-recruited sexually-active individuals and allowing infection of educated
160 susceptible individuals. Furthermore, in this study, the infected individuals who
161 received public health education progress to AIDS at a slower rate in comparison
162 to those who do not.

163 In addition to the aforementioned extensions, this study will contribute to the literature
164 by giving detailed qualitative analysis of the model (1).

165 **2.1 Model Fitting**

166 To test the suitability of the model (1) to effectively enable the assessment of targeted
167 public health education strategies against HIV spread in a population, the model is
168 fitted using data from Uganda as follows. The average lifespan of a Ugandan ($1/\mu$)
169 is assumed to be 50 years (UBSC, 1991) and the recruitment rate (Π) is estimated at
170 3.2% of the total population (UBSC, 1991). The total population of Uganda, as of
171 1990, given by $N=16.7$ millions (UBSC, 1991) is used. The initial conditions used are

172 as follows: $S_u(0) = 14$ million, $S_e(0) = 0.4121$ million, $I_u(0) = 2$ million, $A_u(0) = 0.2$
 173 million, $I_e(0) = 0.087$ million, and $A_e(0) = 0.0009$ million. Thus, the total initial HIV-
 174 infected population (i.e., $I_u(0) + A_u(0) + I_e(0) + A_e(0)$) is 2.2879 million (UNAIDS,
 175 2008), corresponding to 13.7% of the total population. The associated epidemiological
 176 data is presented in Table 2.

177 Using the aforementioned data, the model (1) gives a very good fit of the Ugandan
 178 HIV/AIDS data for the period 1990-2007 (UNAIDS, 2008; UNAIDS/WHO/Unicef,
 179 2008), as depicted in Figure 2. Furthermore, to qualitatively assess the closeness of
 180 the model against the real data, Ordinary Least Squares (OLS) approach is employed
 181 (Kendall & Stuart, 1979). This entails regressing the actual observed data on pre-
 182 dicted cases from the model as follows.

183 Let y_{obs} denotes the observed data. Then, the model prediction (\hat{y}_{pred}) is evaluated
 184 using the OLS regression equation:

$$y_{obs} = \alpha_0 + \alpha_1 \hat{y}_{pred} + \varepsilon, \quad (2)$$

185 where α_0 and α_1 represent the intercept and slope of the regression line, respectively;
 186 and ε account for the random error. The model is said to be “perfect” if the co-
 187 efficients $\alpha_0 = 0$ and $\alpha_1 = 1$ and the coefficient of determination $R^2 = 1$ (which
 188 measures the proportion of variation in the y_{obs}). **Using MATLAB’s Statistical**
 189 **Toolbox, we obtained $\alpha_0 = 0.0636$ and $\alpha_1 = 0.9603$ (with their corresponding**
 190 **95% confidence intervals [0.0261 0.1012] and [0.9380 0.9826], respectively)**
 191 **and $R^2 = 0.9981$ for the above initial data and parameter values in Table 2**
 192 **and 3.** Thus, the OLS regression analysis confirms the closeness of the fit. Hence, the
 193 model (1) can be used to gain realistic insight into HIV transmission dynamics in the
 194 presence of public health education campaign.

3 Model Analysis

Since the model (1) monitors human population, all its associated parameters and state variables are assumed to be non-negative for all $t \geq 0$. Before analysing the model, it is instructive to show that the state variables of the model remain non-negative for all non-negative initial conditions. Thus, we claim the following result.

Lemma 1. *The closed set*

$$\mathcal{D} = \left\{ (S_u, S_e, I_u, A_u, I_e, A_e) \in \mathbb{R}_+^6 : N \leq \frac{\Pi}{\mu} \right\}$$

is positively-invariant and attracting with respect to the model (1).

Proof. Adding all the equations in the model (1) gives:

$$\frac{dN}{dt} = \Pi - \mu N - \delta_e A_e - \delta_u A_u, \quad \text{where } N = S_u + I_u + A_u + S_e + I_e + A_e.$$

Since $\frac{dN(t)}{dt} \leq \Pi - \mu N$, it follows that $\frac{dN(t)}{dt} < 0$ if $N(t) > \frac{\Pi}{\mu}$. Thus, a standard comparison theorem (see Lakshmikantham *et al.*, 1989) can be used to show that $N(t) \leq N(0)e^{-\mu t} + \Pi/\mu(1 - e^{-\mu t})$. In particular, $N(t) \leq \Pi/\mu$ if $N(0) \leq \Pi/\mu$. Thus, \mathcal{D} is positively-invariant. Further, if $N(t) > \frac{\Pi}{\mu}$, then either the solution enters \mathcal{D} in finite time, or $N(t)$ approaches Π/μ . Hence, \mathcal{D} is attracting (i.e., all solutions in \mathbb{R}_+^6 eventually approach, enter or stay in \mathcal{D}). \square

Therefore, the model is mathematically well-posed and epidemiologically reasonable, since all the variables remain nonnegative for all $t \geq 0$. Hence, it is sufficient to consider the dynamics of the model (1) in \mathcal{D} (Hethcote, 2000).

211 3.1 Local stability of Disease-free equilibrium (DFE)

212 The model (1) has a unique disease-free equilibrium, obtained by setting the right-hand
 213 sides of the equations in the model (1) to zero, given by

$$\mathcal{X} = (S_u^*, S_e^*, I_u^*, A_u^*, I_e^*, A_e^*) = \left[\frac{\Pi(1-p)}{\xi + \mu}, \frac{\Pi(p\mu + \xi)}{\mu(\xi + \mu)}, 0, 0, 0, 0 \right], \quad (3)$$

214 It can be shown that \mathcal{X} attracts the region (the stable manifold of \mathcal{X})

$$\mathcal{D}_{\mathcal{X}} = \{(S_u, S_e, I_u, A_u, I_e, A_e) \in \mathcal{D} : I_u = A_u = I_e = A_e = 0\}.$$

215 Using the next generation operator method (van den Driessche & Watmough, 2002),
 216 the associated matrices F_e , for the new infection terms, and V_e , for the remaining
 217 transition terms, are, respectively, given by (noting that $N^* = \frac{\Pi}{\mu}$ at \mathcal{X})

$$F_e = \begin{pmatrix} \beta \frac{S_u^*}{N^*} & \eta_u \beta \frac{S_u^*}{N^*} & \beta(1-\kappa) \frac{S_u^*}{N^*} & \beta(1-\kappa) \eta_e \frac{S_u^*}{N^*} \\ 0 & 0 & 0 & 0 \\ \beta(1-\epsilon) \frac{S_e^*}{N^*} & \beta(1-\epsilon) \frac{S_e^*}{N^*} \eta_u & \beta(1-\kappa)(1-\epsilon) \frac{S_e^*}{N^*} & \beta(1-\kappa)(1-\epsilon) \eta_e \frac{S_e^*}{N^*} \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

218 and,

$$V_e = \begin{pmatrix} K_1 & 0 & 0 & 0 \\ -\sigma_u & K_2 & 0 & 0 \\ -\psi_1 & 0 & K_3 & 0 \\ 0 & -\psi_2 & -\sigma_e & K_4 \end{pmatrix},$$

219 where,

$$K_1 = \mu + \sigma_u + \psi_1, \quad K_2 = \mu + \delta_u + \psi_2, \quad K_3 = \mu + \sigma_e \quad \text{and} \quad K_4 = \mu + \delta_e.$$

220 It follows that the *effective reproductive number*, denoted by R_{eff} , is given by

$$\mathcal{R}_{eff} = \rho(F_e V_e^{-1}) = \frac{\beta(A + B + C)}{K_1 K_2 K_3 K_4 (\xi + \mu)}, \quad (4)$$

221 where ρ is the spectral radius, and

$$A = K_1 K_2 (1 - \epsilon)(1 - \kappa)(p\mu + \xi)(K_4 + \eta_e \sigma_e),$$

$$B = \mu K_4 K_3 (1 - p)(K_2 + \sigma_u \eta_u),$$

$$C = \mu(1 - p)(1 - \kappa)(\psi_1 K_2 K_4 + \psi_2 \sigma_u K_3 \eta_e + \sigma_e \eta_e \psi_1 K_2).$$

222 Biologically-speaking, the effective reproduction number measures the average number
 223 of new infections generated by a single HIV infected person in a community where
 224 a public health enlightenment campaign is used as a control strategy (Anderson &
 225 May, 1991; Hethcote, 2000; van den Driessche & Watmough, 2002). Moreover, in the
 226 absence of public health education ($I_e = A_e = p = \kappa = \delta_e = \xi = \epsilon = \sigma_e = \psi_1 = \psi_2 =$
 227 0), the quantity $\mathcal{R}_{eff} = \frac{\beta(\mu + \delta_u + \eta_u \sigma_u)}{(\sigma_u + \mu)(\mu + \delta_u)} = \mathcal{R}_0$, where \mathcal{R}_0 is the *basic reproduction*
 228 *number* (i.e., \mathcal{R}_0 represents the average number of new cases generated by a single
 229 infected individual in a completely susceptible population).

230 Using Theorem 2 of van den Driessche & Watmough (2002), the following result
 231 is established.

232 **Theorem 1.** *The DFE, \mathcal{X} , of the system (1), given by (6), is locally asymptotically*
 233 *stable (LAS) if $\mathcal{R}_{eff} < 1$, and unstable if $\mathcal{R}_{eff} > 1$.*

234 Theorem 1 implies that HIV can be eliminated from the community when $\mathcal{R}_{eff} < 1$,
 235 provided the initial sizes of the sub-populations of the model (1) are within the domain
 236 of attraction of \mathcal{X} . To ensure that HIV elimination is independent of the initial sizes of
 237 the sub-populations, we need to show that the DFE is globally asymptotically stable
 238 (GAS). This is established in Section 4, for the special case where the efficacy of public
 239 health education is assumed to be 100% (i.e., $\epsilon = 1$).

240 **3.2 Assessment of Impact of Public Health Education**

241 Before using the model (1) to assess the impact of public health education in combatting
242 HIV spread in a population, it is instructive to assess the behaviour of the model under
243 the worst case scenario (i.e., the case where no public health education is provided in
244 the community). By setting all education-related parameters to zero (i.e., $p = \kappa =$
245 $\delta_e = \xi = \epsilon = \sigma_e = \psi_1 = \psi_2 = 0$) and using the data in Tables 2 and 3, simulations of
246 the model (1) show that India, Nigeria, China, Ethiopia, and Russia will record around
247 23.5 million, 12.5 million, 10.1 million, 8.8 million and 6 million total HIV/AIDS cases
248 in eight years, respectively (Figures 3A and 3B). These projections of the model (1)
249 are consistent with the estimates given by the US-based National Intelligence Council
250 (2002), which predicts that, by the year 2010, India, Nigeria, China, Ethiopia, and
251 Russia could have about 20 to 25 million, 10 to 15 million, 10 to 15 million, 7 to
252 10 million, and 5 to 8 million HIV/AIDS cases if the governments of the respective
253 countries do not take serious action against the spread of HIV/AIDS.

254 **3.2.1 Threshold analysis**

255 In this section, the impact of public health education campaign will be assessed by
256 carrying out threshold analysis on the effective reproductive number, \mathcal{R}_{eff} , as follows.

257 Let $\omega = \frac{S_e^*}{N^*}$ be the fraction of susceptible individuals educated at the DFE \mathcal{X} .

258 Hence, \mathcal{R}_{eff} can now be rewritten as a function of ω .

$$\mathcal{R}_{eff} = \mathcal{R}_{eff}(\omega) = \frac{\beta(Z_1 + Z_2)}{K_1 K_2 K_3 K_4}, \quad (5)$$

259 where,

$$Z_1 = \omega K_1 K_2 (1 - \epsilon)(1 - \kappa)(K_4 + \eta_e \sigma_e),$$

$$Z_2 = (1 - \omega)[(1 - \kappa)(\psi_1 K_2 K_4 + \psi_2 K_3 \sigma_e \eta_e + \psi_2 K_2 \sigma_u \eta_e) + K_3 K_4 (K_2 + \eta_u \sigma_u)].$$

Differentiating \mathcal{R}_{eff} , given in (5), partially with respect to ω gives

$$\frac{\partial \mathcal{R}_{eff}(\omega)}{\partial \omega} = -Z_3(1 - \nabla),$$

260 where,

$$Z_3 = \frac{\beta[(1 - \kappa)(\psi_1 K_2 K_4 + \psi_2 K_2 \sigma_e \eta_e + \psi_2 K_3 \sigma_u \eta_e) + K_3 K_4 (K_2 + \eta_u \sigma_u)]}{K_1 K_2 K_3 K_4} > 0, \quad (6)$$

$$\nabla = \frac{K_1 K_2 (1 - \epsilon)(1 - \kappa)(K_4 + \eta_e \sigma_e)}{(1 - \kappa)(\psi_1 K_2 K_4 + \psi_2 K_3 \sigma_e \eta_e + \psi_2 K_2 \sigma_u \eta_e) + K_3 K_4 (K_2 + \eta_u \sigma_u)} > 0.$$

261 Since Z_3 and ∇ are both non-negative (noting that $0 < \kappa < 1$ and $0 < \epsilon < 1$), then

262 $\frac{\partial \mathcal{R}_{eff}(\omega)}{\partial \omega} < 0$ whenever $\nabla < 1$. Further, $\frac{\partial \mathcal{R}_{eff}(\omega)}{\partial \omega} > 0$ if $\nabla > 1$. This result is

263 summarized below.

264 **Lemma 2.** *The use of public health education campaign would have*

265 *(i) a positive population-level impact (reduce disease burden) if $\nabla < 1$;*

266 *(ii) no population-level impact if $\nabla = 1$;*

267 *(iii) a detrimental population-level impact (increase disease burden) if $\nabla > 1$.*

268

269 Biologically-speaking, ∇ could be interpreted as the measure of increase or de-
 270 crease in risky behaviour (or negative attitude) of the individuals in the community
 271 who received public health education. That is, $\nabla < 1$, $\nabla = 1$ and $\nabla > 1$ mean that

272 public health education campaign is able to reduce, cause no change of, and induce
 273 an increase in risky behaviour amongst the individuals who received such education,
 274 respectively. It is worth noting that if the efficacy of public health education is 100%
 275 (i.e., $\epsilon = 1$), then $\nabla = 0$, so that public health education campaign will always have
 276 positive population-level impact. Thus, the detrimental effect of public health educa-
 277 tion is only feasible if it is not perfect ($0 < \epsilon < 1$).

278

279 Alternatively, the impact of public health education campaign can be assessed by
 280 re-writing \mathcal{R}_{eff} as

$$\mathcal{R}_{eff} = \mathcal{R}_0 \left[1 - \Omega \left(1 - \frac{\mathcal{R}_{0e}}{\mathcal{R}_0} \right) \right], \quad (7)$$

281 where,

$$\mathcal{R}_0 = \frac{\beta(\mu + \delta_u + \eta_u \sigma_u)}{(\sigma_u + \mu)(\mu + \delta_u)}, \quad (8)$$

282

283 and,

$$\mathcal{R}_{0e} = \frac{\beta(1 - \epsilon)(1 - \kappa)(K_4 + \sigma_e \eta_e)}{K_3 K_4}. \quad (9)$$

284 The quantity \mathcal{R}_0 is the basic reproduction number (defined earlier) and \mathcal{R}_{0e} is the re-
 285 production number for the case when every individual in the community received public
 286 health education against risky practices that could lead to HIV infection. Furthermore,

$$\Omega = \frac{(\sigma_u + \mu)(\mu + \delta_u)(\gamma_1 + \gamma_2)}{\gamma_3 K_1 K_2 (\xi + \mu) [K_1 K_2 K_3 K_4 (\xi + \mu) \mathcal{R}_0 + \beta(A + B + C)]},$$

287 where,

$$\begin{aligned}
\gamma_1 &= \mathcal{R}_0^2 K_1^2 K_2^2 K_3^2 K_4^2 (\xi + \mu)^2 + \beta^2 (A + B + C)^2, \\
\gamma_2 &= \beta K_3 K_4 (\mu + \delta_u + \sigma_u \eta_u) + (1 - \epsilon)(1 - \kappa)(K_2 + \sigma_e \eta_e)(\sigma_u + \mu)(\delta_u + \mu), \\
\gamma_3 &= \beta K_3^2 K_4^2 (\mu + \delta_u + \sigma_u \eta_u)^2 + (1 - \epsilon)^2 (1 - \kappa)^2 (K_2 + \sigma_e \eta_e)^2 (\sigma_u + \mu)^2 (\delta_u + \mu)^2.
\end{aligned} \tag{10}$$

288 It follows from (7) that the *education impact factor* (denoted by Υ) is given by

$$\Upsilon = \Omega \left(1 - \frac{\mathcal{R}_{0e}}{\mathcal{R}_0} \right).$$

289 Thus, we have established the following result.

290 **Theorem 2.** *The use of public health education campaign in the community will have*

291 *(i) positive population-level impact if $\Upsilon > 0$ ($\mathcal{R}_{0e} < \mathcal{R}_0$);*

292 *(ii) negative population-level impact in the community if $\Upsilon < 0$ ($\mathcal{R}_{0e} > \mathcal{R}_0$); and*

293 *(iii) no population-level impact in the community if $\Upsilon = 0$ ($\mathcal{R}_{0e} = \mathcal{R}_0$).*

294 Numerical simulations of the model, using appropriate demographic and epidemio-
295 logical data for Ethiopia, given in Tables 2 and 3, show the following interesting cases:

296 $\nabla < 1$: Using the aforementioned realistic set of parameter values (Tables 2 and 3), it
297 follows that $\nabla = 0.0517 < 1$, $\mathcal{R}_{eff} = 0.6898$ and $\mathcal{R}_{0e} = 0.6619 < \mathcal{R}_0 = 1.3712$, so
298 that the use of public health education campaign will have positive population-
299 level impact (Figure 4A). In other words, the public health education campaign
300 results in positive behaviour change (in reducing risky practices) in the individuals
301 who received such education (in this case).

302 $\nabla > 1$: Consider the case with $\xi = 0.01$, $p = \psi_1 = \psi_2 = 0.001$ and $\epsilon = 0.4$ (that is,
303 the coverage rate and efficacy of public health education are low) and all other
304 parameters as above. Here, $\nabla = 1.4211 > 1$, $\mathcal{R}_{eff} = 1.5866$ and $\mathcal{R}_{0e} = 1.9857 >$
305 $\mathcal{R}_0 = 1.3712$. The simulation results obtained, depicted in Figure 4B, shows that

306 in this setting, the use of public health education increases the number of HIV
307 cases in comparison to the worst-case scenario. This result could be interpreted as
308 follows: the use of “ineffective” public health education campaign (characterize
309 by low coverage and efficacy) induces an increase in risky behaviour amongst
310 people after receiving it.

311 Contour plots of \mathcal{R}_{eff} as a function of efficacy of public health education and
312 the fraction of individuals who received public health education (i.e., public health
313 education coverage level) at steady-state are depicted in Figure 5. As expected, an
314 increase in efficacy and coverage level leads to a decrease in \mathcal{R}_{eff} . This is an important
315 result because the main objective of public health education is to reduce \mathcal{R}_{eff} as much
316 as possible (since reduction in \mathcal{R}_{eff} is positively correlated with a reduction in disease
317 burden), which could lead to effective disease control or elimination. It is evident
318 from Figure 5 that the prospect of effective control of HIV increases with increasing
319 efficacy and coverage rate of the public health education campaign. For instance, a
320 public health education program with efficacy and coverage level of 60% (each) will
321 fail to control the disease (since $\mathcal{R}_{eff} > 1$ in this case). On the other hand, the use of
322 public health education campaign with efficacy and coverage level of 90% (each) could
323 eliminate HIV from the population (see also Figure 7).

324 **3.3 Evaluation of Targeted Education Strategies**

325 The model is used to evaluate the impact of the following targeted public health edu-
326 cation strategies:

- 327 • Strategy I: educating adult (“established”) sexually-active susceptible individuals
328 only (at the rate ξ),
- 329 • Strategy II: educating a fraction p newly-recruited sexually-active susceptible

330 individuals only,

331 • Strategy III: educating HIV-infected individuals without clinical AIDS symptoms
332 only (at the rate ψ_1), or

333 • Strategy IV: educating HIV-infected individuals with clinical AIDS symptoms
334 only (at the rate ψ_2).

335 Using demographic data from India, Nigeria, China, Ethiopia, and Russia, tabu-
336 lated in Table 3 (together with the associated epidemiological data given in Table 2),
337 simulations of model (1) show that Strategy I can prevent more than 0.8642 million,
338 0.5474 million, 0.3321 million, 0.4064 million, and 0.2116 million new cases in India,
339 Nigeria, China, Ethiopia, and Russia respectively within a year (see Table 4A). Fur-
340 thermore, Strategy I seems to be the most effective amongst all targeted single group
341 strategies. It is also shown that combining Strategies I and IV gives the most effec-
342 tive strategy for reducing new HIV cases in comparison to all other possible 2-group
343 combined strategies. Moreover, Table 4C shows that the combination of Strategy I,
344 Strategy III and Strategy IV is the best in reducing the total number of new cases
345 than any of the others except the universal strategy (i.e., educating every class of un-
346 ducated individuals at a certain rate). The Universal Strategy can prevent more than
347 1.1590 million, 0.7580 million, 0.3858 million, 0.5731 million, and 0.253 million new
348 cases of HIV in India, Nigeria, China, Ethiopia, and Russia respectively within a year
349 (see Table 4D).

350 Table 4 further shows that the use of single-group strategy can be more effective
351 than some 3-group or 2-group strategies. For instance, Strategy I is more effective in
352 reducing the number of new infections than the combination of Strategies II, III and
353 IV. Additionally, a 2-group combined strategy can be better in curtailing the number
354 of new cases than a 3-group strategy (this table shows that combining Strategies I and

355 IV gives fewer new cases than some 3-group strategies, which include the combination
 356 of Strategies I, II and III and also the combination of Strategies II, III and IV).

357 4 Existence of Backward Bifurcation

358 Backward, or subcritical, bifurcation in epidemiological models is typically associated
 359 with the co-existence of disease-free equilibrium and endemic equilibria when the *ba-*
 360 *sic reproduction number* (\mathcal{R}_0) is less than unity. This phenomenon has been found in
 361 many epidemiological settings (see, for instance, Elbasha & Gumel, 2006; Haderler &
 362 van den Driessche, 1997; Kribs-Zaleta & Valesco-Hernandez, 2000 and the references
 363 therein). Furthermore, such phenomenon has been established in a model for public
 364 health education campaign by Mukandavire *et al.*, (2009). The epidemiological impli-
 365 cation of such a phenomenon is that the classical requirement of having the associated
 366 reproduction number less than unity, while necessary is not sufficient condition for
 367 disease control. Following the result in Mukandavire *et al.*, (2009), it is instructive to
 368 determine whether or not the model (1) also undergoes backward bifurcation. This is
 369 explored below.

370 Let,

$$G^{**} = \beta \frac{[I_u^{**} + \eta_u A_u^{**} + (1 - \kappa)(I_e^{**} + \eta_e A_e^{**})]}{N^{**}} \quad (11)$$

be the force of infection at an arbitrary equilibrium of (1), denoted by

$$\mathcal{E} = (S_u^{**}, S_e^{**}, I_u^{**}, A_u^{**}, I_e^{**}, A_e^{**}).$$

371 Thus, at steady-state, the equations of the model (1) can be re-written as:

$$\begin{aligned}
S_u^{**} &= \frac{\Pi(1-p)}{\mu + \xi + G^{**}}, \\
S_e^{**} &= \frac{\Pi(p\mu + \xi + pG^{**})}{(\mu + \xi + G^{**})[(1-\epsilon)G^{**} + \mu]}, \\
I_u^{**} &= \frac{\Pi(1-p)G^{**}}{K_1(\mu + \xi + G^{**})}, \\
A_u^{**} &= \frac{\sigma_u \Pi(1-p)G^{**}}{K_1 K_2 (\mu + \xi + G^{**})}, \\
I_e^{**} &= \frac{G^{**} \Pi(G^{**} C^* + D^*)}{K_1 K_3 (\mu + \xi + G^{**}) [(1-\epsilon)G^{**} + \mu]}, \\
A_e^{**} &= \frac{G^{**} \Pi(G^{**} A^* + B^*)}{K_1 K_2 K_3 K_4 (\mu + \xi + G^{**}) [(1-\epsilon)G^{**} + \mu]},
\end{aligned} \tag{12}$$

with,

$$\begin{aligned}
A^* &= (1-\epsilon)[(1-p)(\psi_2 \sigma_u K_3 + \psi_1 \sigma_e K_2) + K_1 K_2 \sigma_e p], \\
B^* &= \sigma_e K_1 K_2 (1-\epsilon)(p\mu + \xi) + \mu(1-p)(\sigma_e K_2 \psi_1 + \sigma_u K_3 \psi_2), \\
C^* &= [K_1 p + \psi_1(1-p)](1-\epsilon), \\
D^* &= K_1(1-\epsilon)(\xi + p\mu) + \psi_1 \mu(1-p).
\end{aligned}$$

372

373 Substituting (12) into (11), and simplifying, leads to $G^{**} = 0$ (corresponding to the
374 DFE, \mathcal{X}) and the following quadratic equation (in terms of G^{**}):

$$a_{11}^* (G^{**})^2 + a_{12}^* G^{**} + a_{13}^* = 0, \tag{13}$$

375 where,

$$\begin{aligned}
a_{11}^* &= K_3 K_4 (1-\epsilon)(1-p)(K_2 + \sigma_u) + C^* + A^*, \\
a_{12}^* &= K_1 K_2 K_3 K_4 [(1-p)(1-\epsilon) + p] + \mu K_3 K_4 (1-p)(K_2 + \sigma_u) + K_2 K_4 D^* + B^* \\
&\quad - \beta [K_3 K_4 (1-p)(1-\epsilon)(K_2 + \sigma_u \eta_u) + (1-\kappa)(K_2 K_4 C^* + \eta_e A^*)], \\
a_{13}^* &= K_1 K_2 K_3 K_4 (\mu + \xi)(1 - \mathcal{R}_{eff}).
\end{aligned} \tag{14}$$

376 Thus, the following results from the quadratic equation (13).

377 **Theorem 3.** (a) If $a_{12}^* > 0$ then model (1) has forward bifurcation at $\mathcal{R}_{eff} = 1$.

378 (b) If $a_{12}^* < 0$, then the model (1) undergoes backward bifurcation at $\mathcal{R}_{eff} = 1$.

379 **Theorem 4.** (a) If $a_{12}^* > 0$ and

380 (i) $a_{13}^* \geq 0$, the model (1) has no positive equilibrium

381 (ii) $a_{13}^* < 0$, the model (1) has a unique positive equilibrium

382 (b) If $a_{12}^* < 0$ and $a_{13}^* > 0$ and

383 (i) $(a_{12}^*)^2 - 4a_{11}^*a_{13}^* > 0$, the model (1) has two positive equilibria,

384 (ii) $(a_{12}^*)^2 - 4a_{11}^*a_{13}^* = 0$, the model (1) has a unique positive equilibrium,

385 (iii) $(a_{12}^*)^2 - 4a_{11}^*a_{13}^* < 0$, the model (1) has no positive equilibrium.

386 (c) If $a_{12}^* < 0$ and $a_{13}^* \leq 0$, the model (1) has a unique positive equilibrium.

387

388 Since all the model parameters are non-negative (and $0 < \epsilon < 1$, $0 < \kappa < 1$), it is clear
389 that $a_{11}^* > 0$. We consider the following cases:

390 **Case I.** Suppose $\mathcal{R}_{eff} > 1$. Then, clearly $a_{13}^* < 0$. Thus, the quadratic equation (11)

391 is concave up and has two real roots of opposite signs. This implies that the

392 model has a unique positive equilibrium whenever $\mathcal{R}_{eff} > 1$.

393 **Case II.** Suppose $\mathcal{R}_{eff} = 1$. Then $a_{13}^* = 0$ and the quadratic reduces to $G^{**}(a_{11}^*G^{**} +$

394 $a_{12}^*) = 0$, with roots $G^{**} = 0$ (corresponding to the disease-free equilibrium, \mathcal{X})

395 and $G^{**} = \frac{-a_{12}^*}{a_{11}^*}$. Thus, for $\mathcal{R}_{eff} = 1$, the model has a unique positive endemic

396 equilibrium when $a_{12}^* < 0$.

397 **Case III.** Suppose $\mathcal{R}_{eff} < 1$. Then $a_{13}^* > 0$ and equation (13) has either zero, one

398 or two positive real roots. In order to obtain two positive real roots we need

399 $(a_{12}^*)^2 - 4a_{11}^*a_{13}^* > 0$ and $a_{12}^* < 0$. If $a_{12}^* < 0$ and $(a_{12}^*)^2 - 4a_{11}^*a_{13}^* = 0$, then

400 there is one positive real root. Otherwise, there is no positive solution. This
 401 case indicates the possibility of a backward bifurcation in the model (1) when
 402 $\mathcal{R}_{eff} < 1$ (since it suggests the possibility of multiple endemic equilibria when
 403 $\mathcal{R}_{eff} < 1$).

404 It should be noted that Theorem 3 does not give a local description of the bifurcating
 405 curve including its stability. Thus, it is instructive to determine the local behaviour of
 406 the bifurcating branch. Therefore, we alternatively use centre manifold theorem, in line
 407 with Castillo-Chavez & Song (2004), to prove the existence of backward bifurcation.
 408 The proof of the following theorem is given in Appendix.

409 **Theorem 5.**

410 *If (20) holds, then the model (1) has a backward bifurcation at $\mathcal{R}_{eff} = 1$ and the*
 411 *bifurcating branch is unstable near $\mathcal{R}_{eff} = 1$.*

412 To illustrate this phenomenon with respect to the above Theorem, the same param-
 413 eter values for Figure 4B are used and the backward bifurcation diagrams are depicted
 414 in Figure 8. For this set of parameter values, the associated backward bifurcation
 415 coefficients (a and b) have the values: $a = 0.02069982715$ and $b = 1.930595939$.

416 It is worth noting that when $\epsilon = 1$ (i.e., public health education campaign is 100%
 417 effective), the threshold quantity \mathcal{R}_{eff} reduces to

$$\tilde{\mathcal{R}}_{eff} = \mathcal{R}_{eff} \Big|_{\epsilon=1} = \frac{\beta(B+C)}{K_1 K_2 K_3 K_4 (\xi + \mu)}. \quad (15)$$

Similarly, the coefficients of the quadratic (13) reduce to

$$\begin{aligned} a_{11}^* &= 0, \\ a_{12}^* &= K_1 K_2 K_3 K_4 p + \mu(1-p)[K_3 K_4 (K_2 + \sigma_u) + K_2 \psi_1 (K_4 + \sigma_e) + \sigma_u K_3 \psi_2] > 0, \\ a_{13}^* &= K_1 K_2 K_3 K_4 (\mu + \xi)(1 - \tilde{\mathcal{R}}_{eff}). \end{aligned}$$

418 Thus, the quadratic equation (13) becomes linear in G^{**} , with $G^{**} = \frac{-a_{13}^*}{a_{12}^*}$. In this case,
419 the model (1) has a unique endemic equilibrium if and only if $\tilde{\mathcal{R}}_{eff} > 1$ (i.e., $a_{13}^* < 0$)
420 and no endemic equilibria when $\tilde{\mathcal{R}}_{eff} < 1$ (since, in this case, $G^{**} = \frac{-a_{13}^*}{a_{12}^*} < 0$). Hence,
421 backward bifurcation is ruled out in this case (since no multiple endemic equilibria
422 exist when $\tilde{\mathcal{R}}_{eff} < 1$). Alternatively, it can easily be seen that the inequality (20) fails
423 whenever $\epsilon = 1$. This result is summarized below.

424 **Theorem 6.**

425 *The model (1) with $\epsilon = 1$ does not have a positive endemic equilibrium when $\tilde{\mathcal{R}}_{eff} < 1$.*

426 Further, to show that HIV elimination is independent of the initial sizes of the
427 sub-populations of the model when $\epsilon = 1$ (i.e., the efficacy of public health education
428 is 100%), we claim the following result:

429 **Theorem 7.** *The DFE of the model (1) with $\epsilon = 1$ is GAS in \mathcal{D} if $\tilde{\mathcal{R}}_{eff} \leq \frac{S_u^*}{N^*} \leq 1$.*

430 *Proof.* **Consider the model (1) with $\epsilon = 1$. Further, consider the Lyapunov**
431 **function**

$$\mathcal{F} = f_1 I_u + f_2 A_u + f_3 I_e + f_4 A_e,$$

432 **where,**

$$f_1 = (1 - \kappa)[\psi_1 K_2 K_4 + \eta_e \psi_2 \sigma_u K_3 + \eta_e \sigma_e \psi_1 K_2] + K_3 K_4 (K_2 + \eta_u \sigma_u),$$

$$f_2 = K_1 K_3 [\eta_u K_4 + \eta_e \psi_2 (1 - \kappa)],$$

$$f_3 = K_1 K_2 (1 - \kappa) [K_4 + \eta_e \sigma_e],$$

$$f_4 = K_1 K_2 K_3 \eta_e (1 - \kappa),$$

433 **with Lyapunov derivative given by (where a dot represents differentiation**
434 **with respect to t)**

$$\begin{aligned}
\dot{\mathcal{F}} &= f_1 \dot{I}_u + f_2 \dot{A}_u + f_3 \dot{I}_e + f_4 \dot{A}_e, \\
&= f_1 \left[\lambda_u S_u + (1 - \kappa) \lambda_e S_u - K_1 I_u \right] + f_2 (\sigma_u I_u - K_2 A_u) \\
&\quad + f_3 (\psi_1 I_u - K_3 I_e) + f_4 (\sigma_e I_e + \psi_2 A_u - K_4 A_e), \\
&= K_1 K_2 K_3 K_4 \left(\frac{N^* S_u}{S_u^* N} \tilde{\mathcal{R}}_{eff} - 1 \right) I_u + K_1 K_2 K_3 K_4 \eta_u \left(\frac{N^* S_u}{S_u^* N} \tilde{\mathcal{R}}_{eff} - 1 \right) A_u \\
&\quad + K_1 K_2 K_3 K_4 \left(\frac{N^* S_u}{S_u^* N} \tilde{\mathcal{R}}_{eff} - 1 \right) I_e + K_1 K_2 K_3 K_4 \eta_e (1 - \kappa) \left(\frac{N^* S_u}{S_u^* N} \tilde{\mathcal{R}}_{eff} - 1 \right) A_e \\
&\quad - I_u [K_1 (1 - \kappa) (\psi_1 K_2 K_4 + \eta_e \sigma_e \psi_1 K_2)] \\
&= K_1 K_2 K_3 K_4 (I_u + \eta_u A_u + I_e + \eta_e (1 - \kappa) A_e) \left(\frac{N^* S_u}{S_u^* N} \tilde{\mathcal{R}}_{eff} - 1 \right) \\
&\quad - I_u [K_1 (1 - \kappa) (\psi_1 K_2 K_4 + \eta_e \sigma_e \psi_1 K_2)] \\
&\leq K_1 K_2 K_3 K_4 (I_u + \eta_u A_u + I_e + \eta_e (1 - \kappa) A_e) \left(\frac{N^*}{S_u^*} \tilde{\mathcal{R}}_{eff} - 1 \right) \\
&\quad - I_u [K_1 (1 - \kappa) (\psi_1 K_2 K_4 + \eta_e \sigma_e \psi_1 K_2)] \quad \text{since } S_u \leq N \text{ in } \mathcal{D} \\
&\leq 0 \quad \text{for } \tilde{\mathcal{R}}_{eff} \leq \frac{S_u^*}{N^*} \leq 1.
\end{aligned}$$

435 **Thus, $\dot{\mathcal{F}} \leq 0$ if $\tilde{\mathcal{R}}_{eff} \leq \frac{S_u^*}{N^*}$ with $\dot{\mathcal{F}} = 0$ if and only if $I_u = A_u = I_e = A_e = 0$.**

436 **Further, the largest compact invariant set in $\{\mathcal{X} : (S_u^*, S_e^*, I_u^*, A_u^*, I_e^*, A_e^*) \in \mathcal{D} :$**

437 **$\dot{\mathcal{F}} = 0\}$ is the singleton $\mathcal{D}_{\mathcal{X}}$. It follows from the LaSalle Invariance Principle**

438 **(LaSalle, 1976), that every solution to the equations in (1) with initial**

439 **conditions in \mathcal{D} converge to $\mathcal{D}_{\mathcal{X}}$ as $t \rightarrow \infty$. That is, the disease dies out.**

440 **Further, substituting $I_u = A_u = I_e = A_e = 0$ in the model shows that $S_u \rightarrow S_u^*$**

441 **and $S_e \rightarrow S_e^*$ as $t \rightarrow \infty$. Thus, $(S_u, S_e, I_u, A_u, I_e, A_e) \rightarrow (S_u^*, S_e^*, 0, 0, 0, 0)$ as $t \rightarrow \infty$.**

442 **Hence, since the region \mathcal{D} is positively-invariant, it follows that the DFE of**

443 **(1), with $\epsilon = 1$, is GAS in \mathcal{D} for all non-negative initial conditions, whenever**

444 **$\tilde{\mathcal{R}}_{eff} \leq \frac{S_u^*}{N^*} \leq 1$. □**

445 **In summary, it is clear from Theorems 6 and 7 that that the backward**

446 **bifurcation phenomenon of the model is caused by the imperfect nature of**

447 **the public health education campaign (i.e., $0 < \epsilon < 1$). In the case where the**

448 public health education is perfect, $\tilde{\mathcal{R}}_{eff} \leq \frac{S_u^*}{N^*} \leq 1$ is necessary and sufficient
449 condition for the effective control of HIV in the community. In other words,
450 the public health education with perfect efficacy could lead to effective
451 control (or theoretical elimination) of HIV in the community provided the
452 associated threshold quantity, $\tilde{\mathcal{R}}_{eff}$, is brought to (and maintained at) a
453 value less than $\frac{S_u^*}{N^*}$. Thus, this study emphasizes the pressing need for the
454 design of perfect public health education campaign to handle HIV.

455 **Theorem 8.** *The DFE of the model (1) with $\epsilon = 1$ does not undergo backward bifur-*
456 *cation at $\tilde{\mathcal{R}}_{eff} = 1$.*

457 *Proof.* The result follows from Theorem 6, where the model has no pos-
458 itive equilibrium when $\tilde{\mathcal{R}}_{eff} < 1$, and Theorem 7, where the DFE of the
459 model (1) is GAS in \mathcal{D} if $\tilde{\mathcal{R}}_{eff} \leq \frac{S_u^*}{N^*} \leq 1$. □

460 5 Conclusions

461 A realistic deterministic model, which incorporates public health education campaign
462 as a sole intervention strategy for HIV/AIDS prevention, is designed and rigorously
463 analyzed to get insight into its dynamical features and to obtain associated epidemio-
464 logical thresholds. Some of the main theoretical findings of the study are:

- 465 • Under certain conditions, the model (1) undergoes backward bifurcation, when
466 *the reproduction number* (\mathcal{R}_{eff}) is less than unity. The backward bifurcation
467 phenomenon resulted from the imperfect nature of the public health education
468 program.
- 469 • For the case when the public health education program is 100% effective, the
470 disease-free equilibrium of the model (1) is globally-asymptotically stable when-

471 ever the *associated reproduction number* is less than or equal to a quantity less
472 than unity.

473 • Threshold analysis of the effective reproduction number shows that the use of
474 public health education campaign could have positive, no, or detrimental impact
475 depending on whether or not an impact factor, defined as Υ , is less than, equal
476 to, or greater than unity (this result is also expressed in terms of a measure of
477 risky behaviour, denoted by ∇ , given by (6)).

478 The impact of public health education strategies are assessed numerically by sim-
479 ulating the model with a reasonable set of parameter values (mostly chosen from the
480 literature) and initial (demographic) data from five different countries (India, Nigeria,
481 China, Ethiopia, and Russia) where the number of HIV-infected people is expected to
482 grow. Numerical simulations of the model show the following:

483

484 • The universal use of public health education campaign in India, Nigeria, China,
485 Ethiopia, and Russia could avert more than 1.1590 million, 0.7580 million, 0.3858
486 million, 0.5731 million, and 0.253 million new HIV cases within a year, respec-
487 tively.

488 • The universal strategy is more effective than any other strategy in reducing new
489 HIV cases.

490 • Combining Strategies I, III and IV is the next most effective in reducing the total
491 number of new cases (after the universal strategy).

492 • Amongst the 2-group combined strategies, combining Strategies I and IV is most
493 effective than some 3-group combined strategies.

- 494 • Strategy I averts more new cases in comparison to all other single-group strategies
495 (and some 3-group combination of strategies).
- 496 • The prospect of effective control of HIV increases with increasing efficacy and
497 coverage rate of the public health education campaign.

498 Overall, this study shows that an effective public health education campaign which
499 focuses on change of risky behaviour with a reasonable coverage level could help in
500 stemming HIV/AIDS in the countries studied. This requires a concerted effort from
501 all the stake holders especially the governments of the respective countries.

509 **Appendix: Proof of Theorem 5**

510 *Proof.* The centre manifold theorem is used (see Castillo-Chavez & Song, 2004)

511 to show the existence backward bifurcation in the model (1) when $\mathcal{R}_{eff} = 1$. For

512 convenience, let $S_u = x_1, S_e = x_2, I_u = x_3, A_u = x_4, I_e = x_5, A_e = x_6$, so that $N =$

513 $x_1 + x_2 + x_3 + x_4 + x_5 + x_6$. The model (1) can be written as follows:

$$\begin{aligned}
 \frac{dx_1}{dt} &= \phi_1 = \Pi(1-p) - (\xi + \mu)x_1 - \frac{\beta x_1[(x_3 + \eta_u x_4) + (1-\kappa)(x_5 + \eta_e x_6)]}{x_1 + x_2 + x_3 + x_4 + x_5 + x_6}, \\
 \frac{dx_2}{dt} &= \phi_2 = \Pi p + \xi x_1 - \frac{\beta(1-\epsilon)x_2[(x_3 + \eta_u x_4) + (1-\kappa)(x_5 + \eta_e x_6)]}{x_1 + x_2 + x_3 + x_4 + x_5 + x_6} - \mu x_2, \\
 \frac{dx_3}{dt} &= \phi_3 = \frac{\beta x_1[(x_3 + \eta_u x_4) + (1-\kappa)(x_5 + \eta_e x_6)]}{x_1 + x_2 + x_3 + x_4 + x_5 + x_6} - K_1 x_3, \\
 \frac{dx_4}{dt} &= \phi_4 = \sigma_u x_3 - K_2 x_4, \\
 \frac{dx_5}{dt} &= \phi_5 = \frac{\beta(1-\epsilon)x_2[(x_3 + \eta_u x_4) + (1-\kappa)(x_5 + \eta_e x_6)]}{x_1 + x_2 + x_3 + x_4 + x_5 + x_6} + \psi_1 x_3 - K_3 x_5, \\
 \frac{dx_6}{dt} &= \phi_6 = \sigma_e x_5 + \psi_2 x_4 - K_4 x_6.
 \end{aligned} \tag{16}$$

514 The Jacobian of $\Phi = (\phi_1, \phi_2, \phi_3, \phi_4, \phi_5, \phi_6)^T$, around the DFE \mathcal{X} , denoted by J_β , is

515 given by

$$J_\beta = \begin{pmatrix}
 -\xi - \mu & 0 & -\beta H_1 & -\beta \eta_u H_1 & -\beta(1-\kappa)H_1 & -\beta \eta_e(1-\kappa)H_1 \\
 \xi & -\mu & -\beta H_2 & -\beta \eta_u H_2 & -\beta(1-\kappa)H_2 & -\beta \eta_e(1-\kappa)H_2 \\
 0 & 0 & \beta H_1 - K_1 & \beta \eta_u H_1 & \beta(1-\kappa)H_1 & \beta \eta_e(1-\kappa)H_1 \\
 0 & 0 & \sigma_u & -K_2 & 0 & 0 \\
 0 & 0 & \beta H_2 + \psi_1 & \beta \eta_u H_2 & \beta(1-\kappa)H_2 - K_3 & \beta \eta_e(1-\kappa)H_2 \\
 0 & 0 & 0 & \psi_2 & \sigma_e & -K_4
 \end{pmatrix},$$

516 where, $H_1 = \frac{\mu(1-p)}{\xi + \mu}$ and $H_2 = \frac{(1-\epsilon)(p\mu + \xi)}{\xi + \mu}$. It can also be shown from J_β , as in
 517 (4), that

$$R_{eff} = \frac{\beta(A + B + C)}{K_1 K_2 K_3 K_4 (\xi + \mu)}. \quad (17)$$

Consider the case when $\mathcal{R}_{eff} = 1$ and β is chosen as a bifurcation parameter. Solving
 (17) for $\mathcal{R}_{eff} = 1$ gives

$$\beta = \beta^{**} = \frac{K_1 K_2 K_3 K_4 (\xi + \mu)}{A + B + C}.$$

518 Note that the above linearized system, of the transformed system (16) with $\beta = \beta^{**}$,
 519 has a zero eigenvalue. Hence, the center manifold theory Carr (1981) can be used to
 520 analyze the dynamics of (16) near $\beta = \beta^{**}$.

521

522 **Eigenvectors of J_β | $_{\beta=\beta^{**}}$:**

523 The right and left eigenvectors associated with the zero eigenvalue of the Jacobian
 524 J_β evaluated at β^{**} are given, respectively, by $\mathbf{w} = [w_1, w_2, w_3, w_4, w_5, w_6]^T$ and $\mathbf{v} =$
 525 $[v_1, v_2, v_3, v_4, v_5, v_6]$, where

$$w_1 = -\frac{\beta^{**} H_1 \{w_3 + \eta_u w_4 + (1 - \kappa)w_5 + \eta_e(1 - \kappa)w_6\}}{\xi + \mu} < 0,$$

$$w_2 = \frac{\xi w_1 - \beta^{**} H_2 \{w_3 + \eta_u w_4 + (1 - \kappa)w_5 + \eta_e(1 - \kappa)w_6\}}{\mu} < 0,$$

$$w_3 = w_3 > 0, \quad w_4 = \frac{\sigma_u}{K_2} w_3,$$

$$w_5 = w_5 > 0, \quad w_6 = \frac{\psi_2 w_4 + \sigma_e w_5}{K_4},$$

$$v_1 = v_2 = 0, \quad v_3 = v_3 > 0, \quad v_4 = \frac{\beta^{**} \eta_u H_1 v_3 + \beta^{**} \eta_u H_2 v_5 + \psi_2 v_6}{K_2},$$

$$v_5 = v_5 > 0, \quad v_6 = \frac{\beta^{**} \eta_e (1 - \kappa) (H_1 v_3 + H_2 v_5)}{K_4}.$$

To determine the direction of bifurcation, following Castillo-Chavez & Song (2004), we find the signs of a and b , where

$$a = \sum_{k,i,j=1}^6 v_k w_i w_j \frac{\partial^2 \phi_k}{\partial x_i \partial x_j}(0,0) \quad \text{and} \quad b = \sum_{k,i=1}^6 v_k w_i \frac{\partial^2 \phi_k}{\partial x_i \partial \beta^{**}}(0,0).$$

526 It can be shown, after using the associated nonzero partial derivatives of Φ at the DFE
527 (\mathcal{X}), that

$$a = \frac{2\beta^{**}\mu P_{11}}{\Pi(\xi + \mu)}(P_{12} - P_{13}), \quad (18)$$

528 where,

$$\begin{aligned} P_{11} &= w_3 + \eta_u w_4 + (1 - \kappa)w_5 + (1 - \kappa)\eta_e w_6 > 0, \\ P_{12} &= -v_3\mu(1 - p)(w_1 + w_2) - v_5(1 - \epsilon)\{(p\mu + \xi)w_1 + (1 + p)\mu w_2\} > 0, \\ P_{13} &= (v_3\mu(1 - p) + (1 - \epsilon)(p\mu + \xi)v_5)(w_3 + w_4 + w_6 + w_5) > 0, \end{aligned} \quad (19)$$

529 Hence, $a > 0$ iff

$$P_{12} > P_{13} \quad (20)$$

For the sign of b , we substitute vectors \mathbf{v} and \mathbf{w} and the respective associated nonzero partial derivatives of Φ at the DFE into

$$b = \sum_{k,i=1}^6 v_k w_i \frac{\partial^2 \phi_k}{\partial x_i \partial \beta^{**}}(0,0),$$

which gives,

$$b = \frac{(1 - \epsilon)(p\mu + \xi)v_5 + v_3\mu(1 - p)}{\xi + \mu} P_{11} > 0.$$

Variables	Description
N	Adult population
S_u	Uneducated susceptible individuals
S_e	Educated susceptible individuals
I_u	Uneducated infecteds with no AIDS symptoms
I_e	Educated infecteds with no AIDS symptoms
A_u	Uneducated infecteds with AIDS symptoms
A_e	Educated infecteds with AIDS symptoms
λ_u	Force of infection of uneducated individuals
λ_e	Force of infection of educated individuals

Parameters	Description
Π	Recruitment rate of susceptibles
μ	Natural mortality rate
δ_u, δ_e	Disease-induced mortality rates
p	Fraction of educated newly-recruited individuals
ξ	Rate of educating susceptibles
ψ_1, ψ_2	Education rates of individuals in I_u and A_u classes
β	Effective contact rate
η_u, η_e	Modification parameters
ϵ	Efficacy of education in preventing infection
$1 - \kappa$	Reduction in transmissibility of educated individuals
σ_u, σ_e	Progression rates to AIDS classes

Table 1: Description of Variables and Parameters of the Model (1).

Parameters	Nominal value	References
δ_u, δ_e	0.47, 0.04	Gumel <i>et al.</i> , 2006
p, ξ	0.5, 0.5	Assume
ψ_1, ψ_2	0.5, 0.5	Assume
β	0.4	Elbasha & Gumel(2006)
η_u, η_e	1.5, 1.2	Sharomi & Gumel(2008)
ϵ	0.8	Karen & Susan (1999)
$1 - \kappa$	0.3	Assumed
σ_u, σ_e	2.6, 1/15	Gumel <i>et al.</i> , (2006) Hyman <i>et al.</i> , (1999);

Table 4: Total new cases averted within a year using (A) Single targeted public health campaign strategy (B) Pair combination of targeted public health campaign strategies (C) Combination of three strategies (D) Universal strategy. Parameters as in Tables 2 and 3.

Figure 1: Schematic Diagram of the Model (1)

Figure 2: Comparison of observed HIV/AIDS data from Uganda (solid lines) and model prediction (dashed line). Parameter values used are as in Table 2 with $\xi=0.01$, $\psi_1 = \psi_2=0.001$, $p=0.3$, and $\beta=0.325$.

Figure 3: Worst-case scenarios for: (A) China, India and Nigeria; and (B) Russia and Ethiopia. Parameter values used are as in Table 2 with all education-related parameters set to zero.

Figure 4: Simulation of the model (1) showing the total infected population as a function of time, using appropriate demographic and epidemiological data for Ethiopia, given in Tables 2 and 3. Dashed line represents the model with public health education campaign and solid line represents the model without education public health education campaign (i.e., all education parameters are zero). For: (A) $\nabla = 0.0517 < 1$, $\mathcal{R}_{eff} = 0.6898$ and $\mathcal{R}_{0e} = 0.6619 < \mathcal{R}_0 = 1.3712$; and (B) $\nabla = 1.4211 > 1$, $\mathcal{R}_{eff} = 1.5866$ and $\mathcal{R}_{0e} = 1.9857 > \mathcal{R}_0 = 1.3712$, with $\xi = 0.01$, $p = \psi_1 = \psi_2 = 0.001$ and $\epsilon = 0.4$.

Figure 5: Contour plot of \mathcal{R}_{eff} as a function of the fraction individuals educated at DFE (ω) and education efficacy (ϵ). Parameter values used are as in Table 2.

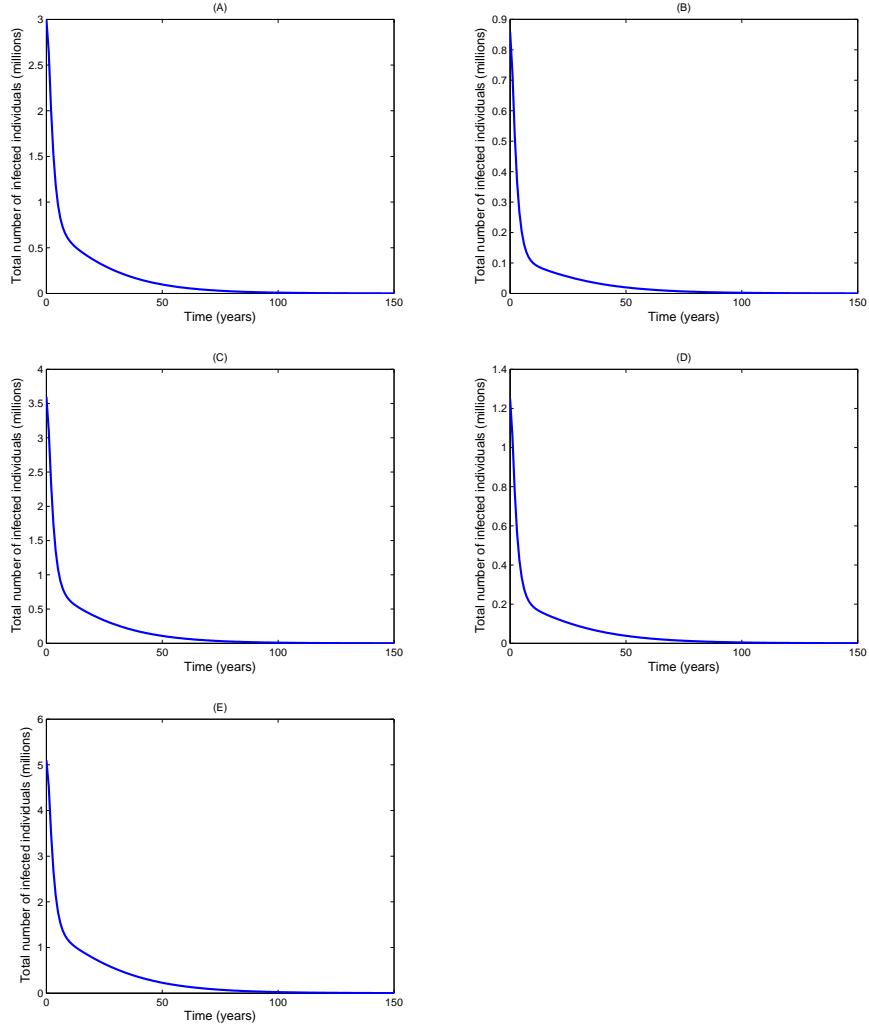

Figure 6: Simulations of the model (1) showing the time needed to eliminate HIV in (A) Ethiopia (B) Russia (C) Nigeria (D) China and (E) India. Parameter values used are as in Tables 2 and 3 with $\xi = p = \epsilon = 0.9$, $\psi_1 = \psi_2 = 0$, $\kappa = 0.8$ and $\beta = 0.2$ (so that, $\nabla = 0.1609 < 1$, $\mathcal{R}_{eff} = 0.1115$ and $\mathcal{R}_{0e} = 0.1103 < \mathcal{R}_0 = 0.6856$).

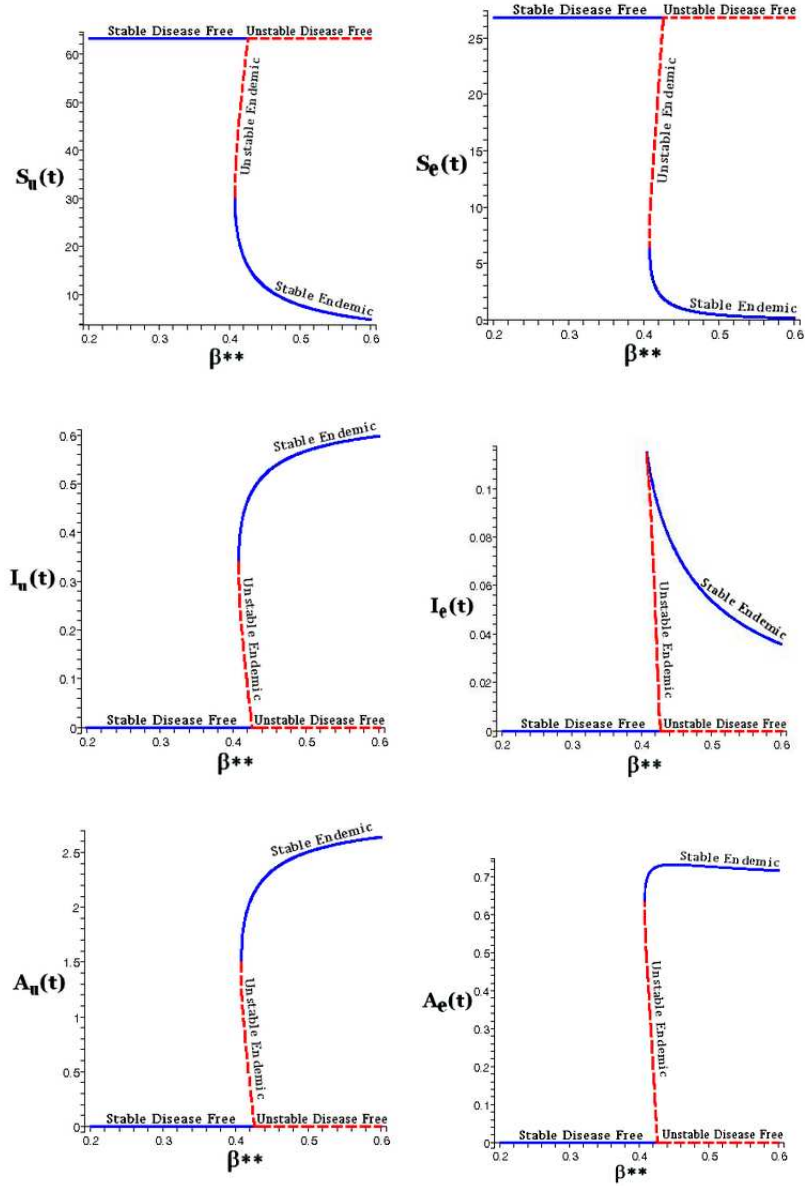

Figure 7: Backward bifurcation diagrams using demographic data from Ethiopia. Parameter values used are as in Table 2 and 3 with $\xi = 0.01$, $p = \psi_1 = \psi_2 = 0.001$ and $\epsilon = 0.4$ (so that, $a = 0.02069982715$ and $b = 1.930595939$).
