# Is Financial Statement Information About Future Earnings Changes Impounded In Returns? 

A Thesis Submitted For The Degree Of Doctor Of Philosophy

By
Eleni Constantinou

Department Of Economics
Brunel University

## ABSTRACT

The thesis provides empirical evidence on the predictive ability and information content of UK financial statement report numbers. Specifically, I investigate the Ou and Penman (1989a) finding for the US that financial statement numbers convey information about the sign of the one year ahead earnings change, and that this is not reflected in current stock returns.

The main motivation, however, of the thesis is the suggestion by Greig (1992) that the Ou and Penman results are driven by variations in accounting ratios across industries. In addition, it is further examined whether the Ou and Penman results are valid only for negative and/or positive values of the earnings changes and whether the Ou and Penman lagged impounding is confined to large and/or companies.

The thesis complements the existing U.K. literature by offering this predictive perspective on, and interpretation of, the incremental information content of financial statement accounting numbers.

The main results of the thesis provide evidence for a "predictive information link" between some annual report numbers and future earnings changes. However, these annual report numbers capture the temporary and not permanent changes in current earnings, thus for the market to look for the incremental information about future earning changes in accounting numbers is not worthy in terms of money and costs. Only, in the stores industry, the $\% \Delta$ in current ratio indeed captures permanent changes in current earnings. The thesis also provides evidence for a "lagged impounding" phenomenon for some of the numbers as well as a "size effect". The incremental information of these accounting numbers is not impounded in current returns. The financial statement information of large companies is earlier reflected in current returns than the information of small companies.

The predictive information link is established by fitting binary one-year ahead earnings change prediction models as well as regression models to annual report data for the period 1980-88. The lagged impounding phenomenon and size effect are established by running multivariate regression earnings information models over the period 1980-88.

I Introduction
II An Overview
III Objective of the thesis
IV Organisation of the thesis
CHAPTER 1 OVERVIEW OF MARKET-BASED ACCOUNTING RESEARCH
1.1 Introduction ..... 1
1.2 The Role Of Accounting In Equity Valuation ..... 2
Basic research on the Earnings/Price Relation ..... 2
1.3 Earnings Response Coefficients Studies ..... 4
Studies on ERC determinants ..... 5
Persistence ..... 5
Beta ..... 6
Earnings Predictability ..... 6
Size ..... 6
Concluding Remarks ..... 7
1.4 Voluntary Differences and changes in accounting Techniques: effects on investors and firms ..... 8
Accounting Cross-Sectional Differences ..... 8
No cash flow effect ..... 8
Direct Cash Flow Effect ..... 9
Concluding Remarks ..... 10
1.5 Evidence suggesting market informational inefficiency ..... 11
Anomalous earnings-price evidence ..... 13
The Price/Earnings Effect ..... 13
Quarterly Earnings Information ..... 14
Annual Report Information ..... 15
1.6 How the market processes information ..... 16
Introduction ..... 16
Analysts' Forecasts ..... 16
The Size Effect ..... 18
1.7 Concluding Remarks ..... 21
CHAPTER 2 HYPOTHESES DEVELOPMENT AND DEFINITION OF THE ACCOUNTING DESCRIPTORS
2.1 Introduction ..... 23
2.2 Gravitation to Fundamentals ..... 23
How Accounting data is regarded as fundamentals ..... 24
2.3 Return to Fundamentals ..... 30
Ou and Penman Financial Statement Analysis ..... 30
Concluding Remarks ..... 31
2.4 The Data ..... 33
Industry Classification ..... 33
The classification of financial ratios ..... 34
Profitability and return ..... 35
Long-term solvency and stability ..... 37
Short-term solvency and liquidity ..... 38
Efficiency ..... 39
Shareholders' investment ratios ..... 41
Formulae for the calculation of ratios used in this study ..... 43
2.5 Estimation Issues Using Ratios ..... 46
2.6 Concluding Remarks ..... 49
CHAPTER 3 DO THE ANNUAL FINANCIAL STATEMENT REPORT NUMBERS CONTAIN INFORMATION ABOUT FUTURE EARNINGS CHANGES?
3.1 Introduction ..... 50
3.2 Experimental Design ..... 51
Introduction ..... 51
3.4 The OP Results ..... 54
3.4 The Results Of This Research ..... 58
Stores Industry ..... 58
Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit ..... 58

## ACKNOWLEDGEMENTS

I would like to express my sincere thanks to Professor Antonios Antoniou for his continuous guidance and support throughout the thesis.

I would like to sincerely thank and express my gratitude to Professor L.C.L Skerratt for his continuous guidance and support throughout the thesis.

I would also like to express my love and thanks to my parents and sister, for their love, continuous encouragement and financial support throughout the thesis.

I would also like to thank my good friends, Demetrios, Charalambos and Rita who have always been there for me when I needed them and a number of people from the Economics department who helped me throughout my thesis.

# Dedicated to my parents, Philippos and Irene and my sister Constantina 

## INTRODUCTION

Research on the usefulness of accounting in equity valuation has emerged from the early work of Ball and Brown (1968) and Beaver (1968) who have shown that accounting numbers supply information for security market investment decisions. Beaver, Lambert and Morse (1980) and Beaver, Lambert and Ryan (1987) and others have also documented that stock prices lead accounting earnings; that is, stock prices can outperform current earnings in predicting next year's earnings. By contrast, the Ou and Penman (1989a), hereinafter OP, controversy has shown that financial statement numbers convey information about the sign of the one year ahead earnings change, and that this is not reflected in current stock returns.

Specifically, the OP conclusions have important implications:

- first, because their results are interpreted as evidence that fundamental analysis works - the summary measure ( Pr ) derived form accounting descriptors in the balance sheet contains information concerning the direction of the changes in one-year earnings per share which is not captured in stock returns;
- second, a delayed stock price reaction to the release of financial statement information may call into question the use of market reaction to evaluate accounting disclosure as in the early work of Ball and Brown (1968).
In addition, the OP conclusion that the market does not fully exploit financial statement information when predicting earnings is closely related to post-earnings announcement drift studies, such as Foster (1974), Freeman and Tse (1989), Bernard and Thomas (1989) and the underreaction findings of Bernard and Thomas (1990) and Abarbanell and Bernard (1992).

However, OP give little or no explanation for their findings. First, there is no economic rationale given to explain why some financial statement numbers predict earnings changes. Secondly, no suggestion is offered as to why there is lagged impounding of the information. OP test for risk but this does not provide an explanation.

These issues of OP findings are dealt with in later work by Holthausen and Larcker (1992), Greig (1992), Stober (1992) and Woodmore (1991). Holthausen and Larcker (1992) find that lagged impounding is period specific, which may explain why
market agents fail to identify the predictive power of some accounting descriptors. Similar time specific resutls are reported by Woodmore (1991) on Australian data.

Greig (1992) suggests that variations in risk and other economic characteristiccs between different industries are driven the OP findings. Since the distribution of the accounting descriptors vary according to industry, the $\operatorname{Pr}$ measure may capture industry specific characteristics and consequently when this measure is used to take long and short positions in a portfolio, it is possible that returns to the portfolio will be influenced by variations in the risk characteristics of the positions taken. Stober (1992) results are consistent with this interpretation.

The objective of this thesis is to investigate whether UK annual financial statements contain information about future earnings' direction and size changes; if they do, whether this information is impounded in the UK current year's stock returns or in the following year's stock returns. There are two significant features of the approach used in the thesis. First, in order to assess whether the OP results might be driven by variations across different industries, the analysis is performed on two industry sectors: stores and chemicals. A second feature, is that the techniques used by Holthausen and Larcker (1992) and Grieg (1992) are combined. The Holthausen and Larcker (1992) technique is followed by investigating the relationship between the accounting descriptors and stock returns directly, rather than indirectly, through the summary measure Pr, as in OP. The Grieg's regression estimation instead of constructing portfolio is being used.

It is further examined whether the predictive information link between the financial statement numbers and future earnings changes is only valid for the negative of positive values of the earnings changes. Last, it is examined whether the predictive ability of the financial statements numbers is driven by either or both large and small companies.

The main results of the thesis provide evidence for a predictive information link between some financial statement report numbers and future earnings changes. However, this predictive ability of the accounting numbers is not consistent over time. It is time-specific. Thus, the financial statement numbers capture only the temporary and not the permanent changes in current earnings. The thesis also provides evidence that the information contained by the financial statements is not always impounded in
the current year's stock returns; that is, there exists a lagged impounding phenomenon in the U.K market as the one reported by Ou and Penman for the U.S.A market. This lagged impounding phenomenon is confined to large companies while there is mixed evidence on whether this lagged impounding is valid only or the positive and/or negative values of the earnings changes.

The thesis is organised as follows:
Chapter 1 reviews the swings in mood in the Capital Markets Research beginning with the Ball and Brown (1968) through early 1990's, to explain why the Ou and Penman (1989a) controversy can be regarded as the most challenging evidence against the maintained market efficiency hypothesis.

Chapter 2

Chapter 3

Chapter 4 investigates the incremental information content of annual financial statement numbers, for stores and chemicals, over earnings during the period 1980-1988 and the subperiods. It also examines whether the ability of financial numbers to contain information about future earnings concerning the direction and size of its next year's earnings change is driven by sudden economic changes (outliers).
Chapter 5 examines whether the information about future earnings changes contained in the annual accounting descriptors, is reflected in the current year's stock returns or in the following year's stock returns.

Chapter 6 explores the background of the research and describes the data that have been used in the empirical tests carried out in this thesis.
investigates whether U.K. stores and chemicals annual financial statement report numbers contain information concerning the direction and size of one-year ahead earnings changes. It provides empirical evidence for a predictive information link between these financial statement numbers and future earnings changes.
concerning future earnings changes is valid only for a particular distribution of the earnings changes. Specifically, an investigation is carried out to test whether the lagged impounding phenomenon is valid only for negative and/or positive values of earnings changes. This is also linked with the activities of financial analysts.

Chapter 7 examines whether the impounding of the accounting information in the following year's stock returns, is caused by the way the market processes information. More specifically, an investigation is undertaken in examining whether the lagged impounding phenomenon is valid for large companies or small companies.
Chapter 8 contains the conclusions, explains the policy implications and describes future research directions.

## CHAPTER ONE

Overview Of Market-Based Accounting Research

### 1.1 INTRODUCTION

Launched by Ball and Brown in 1968, Market Based Accounting Research (MBAR) "the most ambitious research effort in accounting history" [Lev and Ohlson (1982) p. 249], examines one of the most fundamental roles of accounting data: the relation between publicly disclosed accounting information and the value of a firm.

The impetus for this line of research came from the modern capital market disciplines - for example, informationally efficient capital markets, capital asset pricing theory, etc., which provided a widely acceptable and empirically testable link between accounting information and its uses. However, accounting was not and is not only beneficiary but, to a modest extent, a benefactor as well. According to Lev and Ohlson (1982) in both quantity and quality, MBAR is undoubtedly a unique research endeavour in accounting.

The purpose of the chapter is to explain, through summarising the swings in mood in capital markets research beginning with the arrival of Ball and Brown(1968) and ending with the Ou and Penman (1989a) [hereinafter called OP] controversy which is the most challenging evidence against market efficiency. I also suggest what might be causing this controversy in the U.K. stock market.

The controversy involves the proposition that the information in published financial statements can be used to predict future EPS and that from these predictions investors can form portfolios that yield abnormal returns. The controversy is relatively new and is interesting because it explores complex relationships between historical accounting data and future earnings.

### 1.2 THE ROLE OF ACCOUNTING IN EQUITY VALUATION

## Basic research on the Earnings/Price Relation

Research on the usefulness of accounting in equity valuation has emerged from the early work of Ball and Brown (1968) who indicate that positive earnings forecast (sign) errors ${ }^{1}$ are associated with positive unsystematic returns. Conversely, negative earnings forecast errors are associated with negative unsystematic returns ${ }^{2}$. Their analysis has led to an informational perspective on accounting data. This research paradigm considers earnings and other accounting descriptors as explanations of market returns (or unexpected returns). A key concept focuses on unexpected earnings, normalized by the beginning of period stock price, as the primary independent variable ${ }^{3}$ [J. A. Ohlson (1992)].

Ball and Brown (1968) has been extended to examine more subtle hypotheses such as relative association among alternative forecast errors [Beaver and Dukes (1972)] or marginal effects of multiple signals [Brown and Kennelly (1972), Gonedes (1972), Foster (1975) and Griffin (1976)]. However, it took eleven years before the literature considered the magnitude of unexpected earnings as well. It was Beaver, Clarke and Wright (1979) who extended the Ball and Brown's study by incorporating both the sign and magnitude ${ }^{4}$ of the forecast error in their analysis. They concluded that by ignoring the magnitude of the forecast error some of the earnings information content is not reflected. However, they avoided imposing a specific functional form on the price-earnings relation (reliance on rank correlation rather than product moment

[^0]correlations).
Beaver, Lambert and Morse [BLM] (1980) were the first to propose a functional form for the price-earnings relation ${ }^{5}$. Ohlson (1989c) criticised the paper on the ground that it adds little or no insight beyond the Modigliani-Miller dividend valuation model; he argues the literature might be more fortunate if it was built on more general foundation provided by Garman and Ohlson (1980) as the BLM model is "limited because of the absence of a useful distinction between ungarbled earnings and dividends" [Ohlson (1989c), p. 110]. The current literature on "earnings response coefficients" can be viewed as relaxing the restrictive conditions in BLM. However, BLM contribute because they derive the empirical relations from a model that relates security value from a concept of earnings.

A number of papers rely on identical or similar concepts of valuation like the BLM. The BLM study has been extended directly by Collins, Kothari and Rayburn (1987) ${ }^{7}$ who find that price leads earnings to a greater extent for large firms [similar results are reported by Freeman (1987)] and by Beaver, Lambert and Ryan (1987) who assess the information content of security prices with respect to accounting earnings in a reverse regression than that of BLM. They conclude that price changes

[^1]reflect information earlier than earnings do.

### 1.3 EARNINGS RESPONSE COEFFICIENTS STUDIES

In the early 1980's, a new line of research, dealing once more with the issue Ball and Brown (1968), introduces firm characteristics to explain cross-sectional differences in the return/earnings relation.

The factors examined by these studies include size [Atiase (1985)], predictability of earnings [Pincus (1983)], prior information disclosure environment [McNichols and Manegold (1983)]. Although these studies help in understanding differences in the return/earnings relation across firms, they are not in general based on a theoretical formulation of the return/earnings relation.

A step towards improving the specification of the $\mathrm{P} / \mathrm{E}$ relation is made in the earnings response coefficient research arena ${ }^{8}$. This came from finance in the form of the CAPM (Capital Asset Pricing Model) ${ }^{9}$. The Capital Market Research (usually cross-sectional) regression employed is

$$
\begin{equation*}
U R_{i t}=a+b U A_{i t} P_{i t-1}+U_{i t} \tag{1.2}
\end{equation*}
$$

where $\mathrm{UR}_{\mathrm{it}}=$ unexpected return for firm i at period t ; $\mathrm{UA}_{\mathrm{it}}=$ unexpected realization of an accounting number; $\mathrm{P}_{\mathrm{t}-1}=$ price at the beginning of the return period. The slope coefficient is the "earnings response coefficient" which is a Ball and Brown API (Abnormal Performance Index). ERC studies rely on a formal functional formulation between returns and earnings. Empirical studies of ERC can be classified into two groups: [1] studies on ERC determinants and [2] studies on the informativeness of

[^2]earnings. ERC determinant studies typically measure ERC as an association of earnings and returns over a long-term window, and their main focus is to identify factors affecting ERC. Earnings informativeness studies examine the effect of a certain event on the change in ERC. ERC is measured over a short-term window and ERC is used as a measure of earnings informativeness. Former studies are regarded as association studies while the latter as event studies. In the following section, we will be concerned with the former class of studies but not the latter as it is not our main concern.

## Studies on ERC determinants

## Persistence

Earnings persistence measures the degree to which current period earnings shocks persist in the future and affect future earnings expectations. Persistence is usually measured by estimating an ARIMA time series earnings process. Kormendi and Lipe (1987), Easton and Zmijewski (1989a), Collins and Kothari (1989), Lipe (1990) report that persistence is significantly positively associated with ERC. Penman [1992] considers the same theme, but it is different from the previous research in the characterization of "persistence" and in the specification of the earnings variable for which pricing multipliers [Penman uses Pr values similar to the ones used in Ou and Penman (1989)] are estimated in that it does not consider earnings persistence as a permanent, firm specific characteristic of the earnings process and correspondingly earnings response coefficient to be estimated as firm-specific constants. The paper shows that accounting information contributes to the evaluation of persistence and the pricing of earnings innovations and therefore, persistence measures and pricing multipliers do change over time. He concluded that financial statements provide relevant information for the evaluation of earnings changes. Contemporaneous financial statement information indicates the persistence of earnings in the future and leading financial statement information indicates the extent to which earnings have
been anticipated. Further, earnings persistence in general is not a fixed characteristic of firms, but changes over time to become more like that of the typical firm; earnings change multipliers are mean-reverting.

## Beta

The systematic risk, beta, is a determinant of the firm's expected rate of return. Since stock price is assumed to be discounted value of expected future dividends, there exists a negative association between the ERC, systematic risk and risk-free rate of return ${ }^{10}$. Collins and Kothari (1989) and Lipe (1990) report significant negative association between beta and ERC. Easton and Zmijewski (1989a) report a significant partial correlation between ERC and beta. Like beta, a negative association is expected for the risk-free rate of return.

## Earnings Predictability

According to Lipe (1990), earnings predictability is the ability of past earnings to predict future earnings and is reflected in the variance of the earnings shocks in the earning process. Earnings predictability is expected to be positively related with the ERC (as variance of earnings shocks decreases, earnings predictability increases and earnings information becomes more useful in predicting future earnings, resulting in the increase of ERC) [Lipe (1990)].

[^3]
## Size

Easton and Zmijewski (1989a) investigate the correlation between firm size and ERC. The correlation is not significant in every case they examine. Collins and Kothari (1989), in order to control for differential information environment, use size as additional variable and find that the size has no incremental explanatory power over risk in explaining cross-sectional variation in the return/earnings relation.

## Concluding Remarks

Nonetheless, ERC research is still in its infancy. The functional form of the return/earnings relation is extremely restrictive and ERC is measured based on the strong assumption of cross-sectional constancy and/or intertemporal stability of the coefficients. Also, construct validity of theoretical determinants and relations among empirical proxies are not known fully.

According to Bernard (1989) ERC must be used "as a means to another end, such as assessing the improvement of earnings quality by the introduction of certain accounting standards", as soon as, we understand what an ERC is and what factors determine it.

### 1.4 VOLUNTARY DIFFERENCES AND CHANGES IN ACCOUNTING TECHNIQUES: EFFECTS ON INVESTORS, FIRMS AND MANAGERS

The subsequent literature of Ball and Brown (1968) assumed that accounting numbers supply information for security market investment decisions and used this "information perspective" to investigate the relation between accounting numbers and stock prices. This line of research was strictly concerned with whether investors were able to "see through" the veil of accounting techniques changes ${ }^{11}$. The rationale was that rational individuals were not concerned with the "packaging" of information, that is, their beliefs were unaffected by the form of disclosure. Hence, if there were no effects on firms' cash flows then it followed that market values should be unperturbed by firms' choices (cross-sectional differences) or changes in accounting techniques (time-series). The first class of studies to be examined is stipulated by the no impact of accounting changes on cash flows. The next set of studies analyses changes in accounting techniques when cash-flow impacts are present.

## Accounting Cross-Sectional Differences

## No cash flow effect

Beaver and Dukes (1972) examined the association between stock returns and earnings based on both the "deferral" and the "flow through" method of accounting for the interperiod tax allocation. They reported security returns more highly associated with earnings based on the "deferral" method. However, a direct test of investors to adjust for alternative accounting methods was provided by Beaver and Dukes (1973). In this study firms used accelerated depreciation for tax purposes, and for reporting purposes they used either accelerated or straight line depreciation. They reported that investors

[^4]could penetrate the veil depreciation accounting, once the earnings of the straight-line depreciation firms were adjusted to accelerated depreciation since the means of the P/E ratios of the two samples were identical. Similar results were reported by Good and Meyer $(1973)$ and Eskew $(1975)^{12}$. Archibald $(1967,1977)$ examined the stock prices of firms that changed from accelerated to straight line depreciation and concluded that no significant price reaction occurred during the month of earnings announcement.

In 1972, Ball examined the capital market reaction to 267 changes over the 1947-1960 period. The conclusion was that changes in accounting techniques did not appear to be associated with market adjustments in a consistent direction for the average firm. Firms making accounting changes had experienced negative abnormal security returns in the one-year period preceding the accounting change. Harrison $(1977,1978)$ compared the market performance of firms making discretionary as well as nondiscretionary accounting changes with the performance of similar firms that made no accounting changes. Firms which made discretionary changes resulting in earnings increases experienced returns below those of the control group. Moreover, differential security rates of returns between the two samples persisted beyond the disclosure date of the accounting change.

The overall conclusion was that investors were not "fooled" by the switches in accounting techniques.

## Direct Cash Flow Effect

Direct cash-flow effects are generally due to the tax implications of the accounting change. Sunder $(1973,1975)$ reported that firms switching to the LIFO inventory method, i.e decreasing their reported earnings but increasing after-tax cash flows during inflationary periods, experienced positive excess returns in the 12 months

[^5]preceding the announcement of the change. However, for a relatively small sample of firms that switch from LIFO to FIFO Sunder (1975) did not detect the expected negative market reaction. Nevertheless, Sunder's results may have another explanation: as firms tended to switch to LIFO, they incurred the consequent reported-earnings decrease during unusually good earnings periods. So Sunder's observations might be due to the good fortunes of the firms and not to the LIFO switch. Abdel-Khalik and McKeown (1978) classified the LIFO-switching firms into two groups according to the sign of the unexpected earnings change. Firms with positive unexpected earnings that switched to LIFO perform better than a control group, while the firms with negative unexpected earnings that switched to LIFO performed worse than a control group i.e experienced lower stock returns. Findings suggested that investor reaction was associated with the earnings performance of the switching firms rather than with the accounting-method switch. Ricks (1982b) controlling for the fact that adopting firms generally exhibited unusual earnings increases during the examined period 19741975 - Sunder did not control for - found that the LIFO adopting firms experience significantly lower residual returns than a control group during the month of the change announcement. Moreover, he found that when earnings of LIFO firms were adjusted to a FIFO basis, the postswitch P/E ratios of LIFO firms were lower than those of the control group. Brown (1980) reported results consistent with Ricks'.

## Concluding Remarks

The literature concludes that the market "sees through" the accounting to the fundamental variables. But one might ask "What does it see?". The answer might be that it sees through to the cash flows. But what does this mean? Surely, it does not mean dividends. Does it mean cash flows from operations? Free cash flows? But if what is meant is "the present value of future cash flows", there is still confusion between unobservable future cash payoffs and observable information that projects them. Cash flows are, however, the ex post payoffs to wealth (assets). For valuation, one seeks descriptions of ex ante flows - assets that generate cash - and accounting
(at least nominally and probably in reality) provides that in a balance sheet. This is a possible justification for the Ou and Penman use of balance sheet numbers in predicting stock returns.

### 1.5 EVIDENCE SUGGESTING MARKET INFORMATIONAL INEFFICIENCY

The inefficiency in OP to be considered here has a history in the recent literature of market informational inefficiency.

By the mid-1980's, some academics began to realise how little we know about stock market efficiency. Claims by Shiller (1981) that speculative asset prices appear to be much too volatile to be accounted in terms of this efficiency were brought forward. However, Merton (1987), Kleidon (1988), and Cochrane (1991) argued that the tests on volatility are not informative about market efficiency and that volatility tests are another way to show that expected returns vary through time.

The stock market crash of 1987 also shook the faith of some believers [J.V. Horne (Hector 1987) $]^{13}$. Fama (1988), though, argued that the crash has "the look of a permanent adjustment in response to changes in fundamental values". However, the late 1980's found Fama, Fama and French (1988) questioning even the weak form of efficiency: predicting future stock returns based on past stock returns. Their findings evidenced significant serial correlation in returns, when the returns were measured over long ( 3 to 10) years intervals. Campbell and Shiller (1988b) found that E/P ratios, especially when past earnings ( E ) were averaged over 10-30 years had reliable forecast power that also increased with the return horizon. Unlike the long-horizon autocorrelations in Fama and French (1988b) the long horizon forecast power of D/P and $\mathrm{E} / \mathrm{P}$ was reliable for periods after 1940 . The findings might not necessarily reject efficiency but they did not support it either.

[^6]Further research carried on examining whether stock returns were also predictable over short horizons (at least for small firms) based on historical stock returns. In recent work, Lo and MacKinlay (1988) found that weekly returns on portfolios of NYSE stocks grouped according to size showed reliable positive autocorrelation. The autocorrelation was stronger for portfolios of small stocks. This suggested that results may be due to the nonsynchronous effect (Fisher 1966). Lo and MacKinlay emphasized that spurious positive autocorrelation in portfolio returns induced by nonsynchronous closing trades for securities in the portfolio was likely to be more important for portfolios tilted toward small stocks. To mitigate the nonsychronous trading problem, Conrad and Kaul (1988) examined the autocorrelation of Wednesday - to - Wednesday returns for size-grouped portfolios of stocks that traded on both Wednesdays. They found that weekly returns were positively autocorrelated and more so for portfolios of small stocks.

All four results suggested that, because of the variance reduction obtained from diversification portfolios, indications of time variation in weekly expected returns than individual stocks were produced. Their results also suggested that returns are more predictable for small stock portfolios. The evidence, however, was clouded by the fact that the predictability of portfolio returns was in part due to nonsynchronous trading effects that, especially for small stocks, were not completely mitigated by using stocks that trade on successive Wednesdays.

French and Roll (1986) established that stock prices were more variable when the market is open. This was due to a market inefficiency hypothesis that the higher variance of price changes during trading hours was partly transitory, the result of noise trading by uniformed investors (Black 1986). Under this hypothesis, pricing errors due to noise trading were eventually reversed and this induces negative autocorrelation in daily returns.

The odd marriage between psychology and finance can be easily mirrored by DeBondt and Thaler $(1985,1987)$. They mounted an aggressive empirical attack on market efficiency directed at unmasking irrational bubbles. They found that some periods tended to have strong returns relative to the market during the following years,
especially in January of the following years. Conversely, the stocks identified as extreme winners tended to have weak returns relative to the market in subsequent years. They attributed these results to market overreaction to extreme bad or good news about firms. Chan (1988) and Ball and Kothari (1989) argued that the winnerloser results were due to failure to risk-adjust returns (Debondt and Thaler disagree). Zarowin (1989) found no evidence for the Debondt-Thaler (1987) hypothesis that the winner-loser effect was due to overreaction to extreme changes in earnings. He argued that the winner-loser effect was related to the size effect of Bantz (1981); that is, small stocks often losers had higher expected returns than large stocks. Another explanation consistent with an efficient market was that there was a risk factor associated with the relative economic performance of firms (a distressed firm effect) that was compensated in a rational equilibrium pricing model [Chan and Chen (1991)].

## Anomalous earnings-price evidence

The late 1970's and early 1980's also witnessed some accounting anomalies - the size effect, the $P / E$ effect, what appeared to be a delayed reaction to earnings announcements and the unexploited implications of financial statement information for future earnings and abnormal returns.

## The Price/Earnings Effect

Basu (1977) reported that investors would consistently receive excess returns by investing in low $\mathrm{E} / \mathrm{P}$ shares. Even after various adjustments for risks, the low P/E stocks were still superior performers to high $\mathrm{P} / \mathrm{E}$ ratios. Subsequent, questions about the validity of the P/E were raised by other academic researchers in studies of the firm size effect - [Reinganum (1981) and Banz (1981)] who suggested that such results so exist but are derived from size.

In response to the questions raised, Basu conducted a study to re-examine the relationship between the P/E ratio, the size effect, and returns on NYSE stocks for the
period 1963-80. He found that the stocks of low P/E firms generally had higher riskadjusted returns than firms with high P/E ratios. This P/E ratio effect, furthermore, was significant even after differences in firm size were adjusted for. Controlling for differences in both risk and P/E ratios, Basu found that the size effect virtually disappeared. In view of some research suggesting that the P/E effect was confined to low-beta-risk securities, a study by D. Goodman (1985) examined the P/E anomaly with respect to both total risk and systematic risk. The results indicated that the P/E effect was not confined to low-beta-risk securities of the risk measure used. Low P/E securities provided significant positive excess returns across all risk levels.

The P/E ratio anomaly remains unexplained. Until it is refuted, however, it appears to be a potential strategy of investment producing returns superior to other alternatives used.

## Quarterly Earnings Information

Jones and Litzenberger (1970), Brown and Kennelly (1972), Forster (1974), Joy, Litzenberger and McEnally (1977), Watts (1978), Foster, Olsen and Shevlin (1984), Rendleman, Jones and Latane (1987), Bernard and Thomas (1989,1990), Freeman and Tse (1989) and Bartov (1992) and others observed the "drift" in quarterly earnings.

Bernard and Thomas (1990) investigate the market's reaction to quarterly earnings announcements. They found that for a given quarter, the market reacts as if it has the naive expectation that the announcement will be equal to the earnings of the same quarter of the previous year [Len Skerratt (1994) p. 29]. Specifically, Bernard and Thomas document the autocorrelations of seasonally differenced quarterly earnings (quarterly earnings minus the same quarter in the previous year)

| lag1 | lag2 | lag3 | lag4 |
| :---: | :---: | :---: | :---: |
| 0.34 | 0.19 | 0.06 | -0.24 |

and the three day abnormal returns for good news portfolios constructed $\mathfrak{t}$ quarters

| previously | $t=1$ | 2 | 3 | 4 |
| :--- | :--- | :--- | :--- | :--- |
|  | 0.76 | 0.44 | 0.13 | -0.22 |

The similarity between the autocorrelations and the market reactions suggests that the market has naive expectations about the earnings announcements, i.e. the market seems to naively expect that earnings will be equal to those in the same quarter of the previous year.

Why does this happen? Analysts might cause this "inefficiency" through their buy/hold/sell recommendations. They may have incentives to play down changes in earnings [Trueman (1994)]. Moreover, although agents may have information, their major objective may be to anticipate changes in the beliefs of others.

## Annual Report Information

Ou and Penman (1989a,b) pose the question of what role financial variables play in assets valuation and propose a more general version of this hypothesis. They hypothesize there is underutilised information about future earnings contained in a variety of financial statement variables, not just in current earnings. However, there is no theoretical support for the OP proposition. OP did this intentionally, explaining that this is the way investors might use the accounting information. A potential approach to give support to the OP results could be found in the Ohlson's 1991 model (see equation 2.2 p. 25 of the thesis); however at present it gives a rationale for total book value, rather than a particular accounting descriptor.

They develop a LOGIT model for predicting changes in annual EPS one year ahead, using publicly-available financial statement information. They select 28 financial-statement variables ( 16 in one subperiod and 18 in the other, with only six in common) from 68 variables. The model parameters then are fitted to subsequent (i.e out-of-sample) values of firms' financial statement variables to generate predictions of future earnings. Predictions are based on the estimated LOGIT probability of a future earnings increase, denoted Pr . This variable is ranked in pooled cross-section and time-series and extreme observations are selected by a trading rule. Ou and Penman use a strategy of long positions in the $45.3 \%$ of stocks with the highest predicted probability of an earnings increase and short positions in the lowest $10.8 \%$
weighted to produce zero net investment. They report estimated out-of-sample abnormal returns from this strategy over 1973-83. These average $+8.3 \%$ in the first year after the EPS predictions are made, $+6.2 \%$ in the second year and $6.3 \%$ in the third. Ou and Penman conclude that financial statements capture fundamentals that are not reflected in prices.

Ou and Penman's results are replicated, albeit with some qualifications and with a more sceptical interpretation in three studies: Greig (1992), Holthausen and Larcker (1992), and Stober (1992) for U.S.A data while Woodmore (1991) investigates the issue for the Australian market.

### 1.6 HOW THE MARKET PROCESSES INFORMATION

## Introduction

Overviewing capital markets research, the underreaction to financial statements seems to be the most challenging evidence against market efficiency. The underreaction to financial statements is an interesting empirical irregularity. The obvious question posed is Why does it exist and whether there is anything systematic about it. The answer might lie in the way the market processes information. For example, the answer might lie in the incentives of analysts who, for example, like to maintain good relations with managers - or in psychological forces that are not likely to be strongly influenced by incentives - for example, analysts' personal theories of earnings. A second possible explanation might involve transaction costs as well as firm size.

## Analysts' Forecasts

An emerging theme of this line of research is to investigate what information appears to be impounded in analysts' forecasts. The motivations are closer to a decision context since they include uncovering the sources of analysts' forecast superiority
relative to mechanical models - for example, Brown, Griffin, Haggerman and Zmijewski - and testing for whether analysts appear to make full and rational use of all information available to them. Brown, Hagerman, Griffin and Zmijewski (1987) find that analysts' forecasts are better if based on Value Line since they have highest association with abnormal returns and relation of abnormal returns with unexpected earnings based on size and recent forecasts are better.

An example of research into the factors which generally determine, or at least are generally associated with, analyst earnings forecasts superiority is Bhushan (1989) who finds that number of analysts following is positively related to firm size, return variability of firm, squared correlation between firm's return and market return and inversely related to the number of lines of the business. Atiase (1985), and Freeman (1987), also examining the cross-sectional variation in the information content of earnings announcements, find an inverse relation between information content and firm size and researchers have linked this finding to differences in analyst following of firms. Many of these studies argue that larger firms are followed by more analysts, which results in greater private information acquisition about these firms [Brown, Richardson and Swager (1987)]. However, financial analysts' superiority is weaker for certain industries (i.e. petroleum) and for particular periods.

Also recent investigations of information used by analysts have begun to focus on whether analysts' forecasts and forecast revisions appear to impound all the information in prior stock price changes and earnings releases, and whether forecasts contain information even when they are associated in time with either other forecasts or firm-specific disclosures. With regard to competing disclosures, Lys and Sohn (1990) conclude that analysts' forecasts are based on information partly independent across analysts and partly independent of corporate disclosures. Both Klein (1990) and Abarbanell (1991) confirm Lys and Sohn's results.

A related series of studies examining how analysts respond to earnings information instead of share price change information, in making and revising forecasts [Mendenhall (1991), Abarbanell and Bernard (1991)] find that analysts underreact to earnings information in forming their forecasts. Analysts set overly
optimistic estimates of the next period's annual EPS and forecast errors display significantly positive serial correlation. These results hold for short-term as well as for longer term IBES consensus forecasts. The findings suggest that analysts are able to differentiate partially between permanent and temporary components in previous period earnings. Also the overestimation bias and serial correlation are not uniform across firms; furthermore, the results support the view that analysts do not utilize available information efficiently when setting forecasts.

Understanding analysts' incentives in forecasting earnings might call for the need to examine what the analysts do. Brett Trueman (1994) argues that under certain circumstances an analyst prefers to release a forecast that is close to prior earnings expectations, even if issuing a more extreme forecast is justified by his private information. Such action positively impacts investors' assessment of the analyst's forecasting ability and so enables him to charge a higher fee for his forecasts. Second, the likelihood that the analyst releases a forecast similar to those previously announced by other analysts is greater than could be justified by his own information. Such action is a manifestation of herding behaviour and is undertaken in order to favourably affect investors' assessment of the analyst's forecasting ability.

## The Size Effect

One area where a growing stream of evidence has arisen to suggest an apparent inefficiency is the "firm size effect".

In a well publicized study, Bantz (1981) finds that the stocks of small NYSE firms earned higher risk-adjusted returns than the stocks of large NYSE firms. Bantz finds a negative association between average returns to stocks and the market value of the stocks after controlling for risk.

This empirical finding prompted a number of researchers, amongst which Reinganum (1981), to see whether there is any interrelationship between the "size effect" and other empirical anomalies apparent in stock return data. Reinganum
concludes: "after controlling returns for any P/E effect, a strong firm size effect still emerged. But after controlling returns for any market value effect, a separate $\mathrm{P} / \mathrm{E}$ effect was not found".

The papers by Bantz (1981) and Reinganum (1981) have drawn a lot of attention and a number of papers have analyzed the statistical tests used in these two papers. According to Schwert (1983) papers trying to analyze "size effect" fall into three categories: [1] "papers that look for an explanation of the findings of Bantz (1981a) and Reinganum (1981) in measurement of statistical testing errors; [2] papers that provide more detailed characterization of the "size effect"; and [3] papers that propose an economic explanation of the evidence."

In the first group of "size effect" as a statistical artifact, Roll (1981) argues that the stocks of small firms are traded less frequently than those of large firms, thus estimates of systematic risk from daily stock returns will be biased downward. However "both Roll and Reinganum (1982) conclude that the bias in risk estimates due to non-synchronous trading cannot explain the magnitude of the risk-adjusted returns found by Reinganum (1981a).

In 1983, Basu re-examines Reinganum's (1981a) results using both different sample period and different way for forming portfolios of stocks on both size and earnings/price ratios. Basu (1983) results contradict Reinganum's (1981a) conclusion that the "size effect" subsumes the E/P effect. He argues that there is indeed some interaction between size and $\mathrm{E} / \mathrm{P}$ ratios: the magnitude of risk-adjusted returns is largest for small firms with high E/P ratios.

In the second group, having observed that small firms have higher returns than large firms and that returns in January are higher than in any other month of the year, Keim (1983) finds that the January effect has been due primarily to the behaviour of small firms and the size effect has been concentrated mainly in the month of January. Further examination of this interrelationship between the size effect and the January effect has shown that it is concentrated in the first five trading days in January.

Brown, Kleidon and Marsh (1983) examine the behaviour of "size effect" over time, throughout the sample period 1967-79 and find a negative excess return between

1969-73 for small stocks and a positive excess return for the period 1974-79.
Attempts to explain this interrelationship between the "January effect" and the "size effect" appearing to have some merit have to do with "tax selling" [Roll (1977, Reinganum (1983), Lakonishok and Smidt (1986)].

Keim and Stambaugh (1984) extend the previously mentioned studies of the day-of-the-week effect back to 1928 and negative Monday returns are documented over the 55 -year period. However, there is no systematic relationship between portfolio size and the size of the Monday return.

A second explanation is that small stocks may be relatively riskier in January, thus they should have a relatively higher average return in January. Two studies lending support to this argument are Rogalski and Tinic (1986) and Arbel (1985).

In 1987, Freeman argues that the market seems to impound information about large firms much quicker than about small firms. This means there is greater scope for insider dealing with small firms. Consequently, investors may be reluctant to invest in smaller companies, making a bias towards larger companies. According to CKR and Freeman, the benefits of shareholders of small firms are much larger than those of larger firms.

Also, Atiase (1985) and Bhushan (1989) find an inverse relation between information content and firm size; and researchers have linked this finding to differences in analyst following of firms. Many of these studies argue that larger firms are followed by more analysts, which results in greater private information acquisition about these firms.

Other papers have examined the magnitude of transaction costs for stocks of firms in different size categories [Stoll and Whaley (1983), and Schultz (1983)]. Stoll and Whaley (1983) examining monthly returns of NYSE-listed stocks from 1960 to 1979 for ten portfolios ranked on market value of the stocks, find that small stocks tend to have lower prices and higher bid-ask spreads, so transaction costs are relatively high for these stocks. They estimate risk-adjusted returns to the small firm portfolio net of transaction costs and find that a round-trip transaction every three months is sufficient to eliminate the "size effect". However, Schultz (1983) examining daily
returns to NYSE-listed and AMEX-listed stocks from 1963 to 1979 finds similar results to those of Stoll and Whaley (1983). However, he also estimates average transaction costs for each month and finds no evidence of seasonality that could explain the "January size effect" found by Keim (1983). Schultz's conclusion is that transaction costs cannot explain the high average returns to small firms' stocks.

### 1.7 CONCLUDING REMARKS

In the late 1960 's and early 1970 's, the belief that the market is efficient is very strong and we experience a number of event studies investigating what information accounting pertains. However, by the mid 1980's, academics realise how little we know about market efficiency and the appearance of market anomalies - $\mathrm{E} / \mathrm{P}$ ratio, size effect, the crash of 1987 , volatility - and perhaps the most challenging evidence against efficiency, the underutilisation of financial statements, shake the faith in market efficiency. The question becomes then whether the market is efficient or not.

Thus, entering the late 1980 's and early 1990's the question posed is no longer whether the market is efficient, but how the market processes information (i.e impounding of information in current prices or not impounding). A turn to the traditional issues is witnessed, with emphasis on the relation between earnings and prices and the information content of earnings and non-earnings data.

It is high time, the issue of why the price is used as a measure of value was questioned. Lev and Ohlson (1982) call for more research on asset valuation by fundamental variables and reveal their surprise for why the MBAR has been almost exclusively concerned with the association between financial data and stock-price changes (returns) while ignoring the more basic question of asset valuation by fundamental (accounting variables).

The issue of valuation by fundamental variables is obviously of considerable importance both in examining what the marginal contribution of accounting information in general and for specific data, relative to other information sources to determining capital is. Every day thousands of investors ask themselves what price they should pay for firms or shares of firms. Presumably, they attempt to know how to utilise the information found in financial statements in making these pricing decisions. An understanding of how one can use the financial statement information in assessing how much a firm is worth would clearly be an important contribution. Ou and Penman (1989) financial statement analysis, although crude, focus on our thinking of how accounting information can be used by investors.

## CHAPTER TWO

## Background of the Research And Definition Of The Accounting Descriptors

### 2.1 INTRODUCTION

The purpose of this chapter is to explain how the hypotheses tested in the subsequent chapters are developed and what data have been used in the empirical tests.

In the previous chapter, we note that Lev and Ohlson (1982) propose a return to fundamentals. Lev and Ohlson (1982) call for more research on asset valuation by fundamental variables and reveal their surprise for why the MBAR has been almost exclusively concerned with the association between financial data and stock-price changes (returns), while ignoring the more basic question of asset valuation by fundamental (accounting variables).

Bernard (1989) argues that in the work of Penman, Ohlson and others, research can help us understand what can be learned from accounting and how the accounting system serves to enhance financial statement analysis ${ }^{1}$.

### 2.2 GRAVITATION TO FUNDAMENTALS

Ou and Penman (1989a) attempt to focus our thinking of how to infer investment worth from accounting data, exploiting the aggregation and measurement properties of accounting. Specifically, they address the exact relationship between investment worth and accounting data.

The following section provides an explanation of how the book value in accounting data can be regarded as being relevant to fundamental analysis which OP carried out for the U.S.A market.

[^7]
## How Accounting data is regarded as fundamentals

The justification by OP of the use of accounting data in fundamental analysis is through the use of accounting as a value measurement system.

In 1979, Beaver and Demski (BD) attempt to see how economic income might be useful to investors. Then they try to assess the role of income measurement using time state preference theory. The upshot of the BD analysis is that if the real asset markets are competitive and perfect, then investors by observing values recorded in the real market can easily work out the value of the corporation and its economic income. This means that the firm does not need to disclose its economic income to the financial markets. Thus, in these circumstances, economic income is redundant; or at least, the rationale for disclosing must rely on "cost effective" communication, that is, economies of scale in information production. Essentially, the argument is that perfect and competitive markets assume perfect information. In this world, there is little room for accounting; investors are assumed to have no information problem. This is like trying to analyse the demand for cars, making the assumption that nobody needs to travel.

From the BD paper, it looks as if accounting (based on economic income) is either redundant or useless. However, this assumes that accounting is concerned with valuation. Peasnell (1982) argues that valuation is something which gets done in markets and that the role of accounting is to supply the markets with the necessary information. This notion is taken up wholeheartedly by Demski and Sappington (1990). Demski and Sappington suggest (although they do not see it like this) that accounting information can be used to assess the longevity of earnings (i.e. the extent to which earnings might be repeated in perpetuity). However, they do say that accounting has an informational role as well as a valuation capacity. This is in effect, a justification for the financial statement analysis. That is, accounting numbers can provide information about the future of the enterprise dependent on various states of the economy. The longevity of earnings is just one example of what DS have in mind. The view that accounting should shed light on the persistence of earnings is taken up by Ohlson in a number of papers (1991). James Ohlson links fundamentals with
market values while Ou and Penman paper (1989a) is the implementation ${ }^{2}$.
If investment worth cannot be assessed by deferring to price, then the following equation might give an understanding of how accounting operates as a value measurement system.

$$
\begin{equation*}
P_{t}=\sum_{\tau=1}^{\infty} \rho^{-\tau} E\left(d_{t+\tau_{z}}\right) \tag{2.1}
\end{equation*}
$$

where $P_{t}$ is the price at time $t, d_{t+\tau}$ is the dividends paid at ${ }_{t+\tau}, E$ the expectation operator, $Z_{t}$ the information at date $t$ and_ $\rho$ the rate at which expected future dividends are discounted (plus one). This is the dividend capitalisation formula of Williams (1938). Rubinstein (1976) provides the generalisation of this formula using minimal assumptions. This representation directs the task of financial statement analysis. The financial analysis question is how accounting might be helpful in escaping the dividend conundrum.

Accounting has two features that might help escape the dividend conundrum ${ }^{3}$ : it is a system recording transactions bound by rules independent of stock prices and dividends; it is connected to future dividends, the target attribute of equation 2.7.4 On face value, accounting is a system of measuring value and value accretion. Accounting is not just a signal but a measure of change in value. Ohlson $(1988,1991 a)$ has produced a breakthrough. Ohlson has shown

$$
\begin{equation*}
P_{t}=y_{t}+\sum_{j=1}^{\infty} E_{t}\left[x_{t+j}^{a}\right] R_{f}^{-j} \tag{2.2}
\end{equation*}
$$

where $y_{t}$ is the book value of assets, $x_{t}^{a}$ is the excess earnings on the book value of assets in place at $t-1$ and $R_{f}$ is the $1+$ the risk free rate. The condition to get from equation 2.1 to 2.2 is that earnings are calculated using clean-surplus accounting. That

[^8]is, changes in owners' equity due to reasons other than capital contributions and dividends are run through the income statement and dividends are against owner's equity but not earnings. In this model the value of the firm is related to
$\bigcirc \quad$ the book value of existing assets and
$\diamond \quad$ the excess earnings on the current capital stock (as measured by the book value).

This approach identifies that different points in time will give rise to different excess earnings; it takes account of the fact that earnings will not be sustainable in perpetuity. Value is based on projections of future accounting earnings from current information. Unlike dividends and cash flows earnings aggregate in a value sense. One does not have to worry about timing since the task is to predict the total earnings that a firm will deliver to the horizon and not earnings of the following year. Thus "manipulation" of income using accounting policies is of no concern if it just results in timing differences working their way out by period $\mathrm{t}+\mathrm{j}$.

This reflects the aggregation property of accounting which the formula captures. One "capitalises" aggregated future earnings [Ohlson (1990)] as the present value of earnings is not equal to the present value of dividends in [2.1] except in the case of $100 \%$ dividend payout every period. Future dividends do not have to be predicted. The relationship lies in that if dividends are paid out in the future, expected subsequent earnings are reduced. Dividends appear in the formula because they affect future earnings and, although by themselves, they are irrelevant for value ${ }^{5}$. One can consider future earnings as if no dividends are paid earnings reflect earnings as if all dividends are reinvested in the firm.

The Capital Markets Research argues that accounting earnings are not value relevant but information about value attributes (future dividends) [Ball and Brown (1968)]. Equation 2.1 says that adding earnings adds value and over a long horizon,

[^9]this is dollar for dollar. This involves earnings as a measure of change in value and this view of accounting as a system for aggregating value is supported by Easton and Harris (1991), Easton, Harris and Ohlson (1991) and Ohlson and Penman (1991).

In the OP model, the link between market value and book value is through the earnings number. The book value of assets provides information about future earnings, which in turn generates value.

However, using the earnings number might be problematic. In OP(1989) paper, three problems can be identified with the use of earnings:
$\diamond \quad$ OP use individual ratios and not Ohlson's suggestion of the total assets [see equation 2.2].
$0 \quad$ OP use earnings as an intermediate step to predict earnings one-year ahead. Holthausen and Larcker (1992) argue that earnings are only weakly correlated with returns [Larcker 1989)] and therefore, they examine the ability of accounting information to generate profitable trading strategies by a model directly predicting the sign of subsequent one year excess return measures ${ }^{6}$.
$\diamond \quad$ OP carry out a financial statement analysis. Carrying out a financial statement analysis, there is always the problem that financial ratios might be misleading, if the ratio assumptions are not satisfied. This makes the financial statement analysis not working. Thus, attention should be drawn on what assumptions ratios have to satisfy and the possible problems encountered when dealing with accounting ratios. The basic assumption of ratio analysis is that of strict proportionality between the numerator and the denominator [Lev and Sunder (1979)]. The strict proportionality is assumed both in comparisons of ratios across firms at a point in time as well as over time. X and Y are strictly proportional i.e $\mathrm{Y}=\mathrm{BX}$ and the ratio becomes $\mathrm{Y} / \mathrm{X}=\mathrm{B}$. However, the strict proportionality is violated if (i) there is an intercept term, a, and $a=0$ so that $Y / X=b+a / x$ e.g an element of firm's profit may be unrelated to the sales element so the profit/sales ratio is not an adequate description of the relationship

[^10]between profit and sales. Whittington (1980) and Barnes (1982) identify the nature and likelihood of misinformation arising from (i) and suggested that regression analysis should be used. McDonald and Morris $(1984,1985)$ present evidence that the proportionality assumption is not violated and the ratio model was to be preferred. McLeay and Fieldsend (1987) conclude that it "remained tenable" allowing for size and sector effects identified by Lee (1985) and Buijink and Jegars(1986); (ii) where there is an error term, e , in which cases $\mathrm{y}=\mathrm{a}+\mathrm{bx}+\mathrm{e}$ i.e the variance u changes over time (heteroscedasticity).

Much of the analysis of the distribution of financial ratios focuses on the normal distribution because
$0 \quad$ it is described by only two statistics i.e mean and standard completely specify the distribution;

- many statistical tools available for analysing financial statement data are based on the assumption that data are normally distributed.
However, reasons exist for expecting non-normality. These involve [a] skewness in the distribution if strict proportionality does not hold; [b] some financial ratios e.g current ratio, have technical limits preventing a normal distribution from being a literal description; [c] some financial ratios have economic limits resulting in fewer observations in either the lower or upper end of the distribution than under normal distribution.

Since the earnings figure and ratio analysis might be problematic why not using the Discounted Cash Flow analysis (DCF). As Copeland, Koller and Murrin argue "the DCF approach captures all the elements that affect the value of the company in a comprehensive yet straightforward manner". But how does one define cash flows? Dividends are the cash flows paid to shareholders, but we cannot deal with these. What is meant, is firms' internal cash flows? But where do we observe these? In the financial statements. But where and what number? Is it the cash flows from operations? No, because it does not take out investment (like earnings do through depreciation). Is it "free cash flow? (operating cash flow minus investment)". This takes care of investment but the calculations to get to the number from the published financial statements are not trivial. Accounting obscures the real cash flows with
accrual noise. This is the problem with accounting.
However, on the other hand, free cash flow concerns the distribution of wealth rather than its generation. It is the maximum dividend a firm pays after providing for investment. Like dividends it is uninformative and as Paton (1963) said "cash flow is an illusion".

Cash flows do not aggregate like a value measure should. DCF has no way of handling stocks at the end of the period that generate subsequent cash flows i.e no prediction over finite period. Accounting does this automatically as book values at the end of a period are aggregations of prior earnings (ex-dividend) that represent a stock of value (assets) capable of generating future earnings and dividends.

If accept these deficiencies then DCF analysis works as an ex ante valuation model. However, to develop a fundamental analysis one has to discover empirical relationships between current information (for example, at period $t$ ) and future value attributes at $t+\tau$ for all_ $\tau>0$. If those attributes are future cash flows this is not possible as Ohlson (1990) points out, realized cash flows at $\mathfrak{t}+\varsigma$ reflect not only cash flows projected at time $t$ but also cash flows from investments made between $t$ and $t+\tau$. Ex post there is no way of disentangling them.

Again as ex post cash flows are uninformative, it is the same as forecasting dividends: value can be expressed as the present value of future cash flows but observed cash flows are uninformative about value. Accounting takes out this problem by distinguishing wealth appreciation from dividends and adjusting for financing through the per-share calculation.

### 2.3 RETURN TO FUNDAMENTALS

The equation 2.2 focuses our thinking: where will accumulated earnings (book values) be in 5,10 or 15 years? The task is one of efficiently summarising information that gives answer to this question. To do this, a large array of data - sales, depreciation..., as well as information outside the financial reports will have to be evaluated. Not only will we have to identify what pieces of information need to be considered but also the weights to apply to the pieces to project what is essentially a point estimate of future earnings. These weights may differ under different circumstances - firms, industries, economy and this aggregation might not be easy. So how can it be achieved?

One can turn to the aggregation and measurement properties of accounting. Financial statements involve a great deal of information about a company. Accounting procedures aggregate a large amount of information (transactions) into summary measures. They are, at least, at face value, value measures. One might start with these numbers and add other information only if it indicates value (expected future earnings or book values) not captured by these measures.

But why choosing earnings? Since the task is the prediction of future earnings, current earnings may well be a good indicator of future earnings. What follows is an approach to financial statement analysis that takes this summary measure as a starting point and thus exploits accounting aggregation [Ou and Penman(1989)].

## Ou and Penman Financial Statement Analysis

Ou and Penman (1989a) examine the information in the balance sheet about future profits whether or not such information is impounded in prices. The study can be interpreted in terms of both (i) permanence of earnings and also (ii) information about the excess opportunities from future investment.

OP develop a LOGIT model for predicting changes in annual EPS one year ahead using publicly available financial statement information. They construct a Pr measure from non-earnings numbers in the financial statement (e.g the balance sheet and footnotes). They select 28 financial statement variables (16 in one subperiod and

18 in the other, with only six in common) from a wide set of 68 variables, purely on the basis of their ability to predict earnings. Those selected include return on assets, return on equity, $\Delta^{7}$ in return on opening equity, debt/equity ratio, $\% \_\Delta^{8}$ in dividend per share and $\% \_\Delta$ in inventories. The model parameters are then fitted to subsequent, that is, out of sample, values of firms' financial to generate predictions of future earnings. Predictions are based on the estimated LOGIT probability of a future earnings ( $E_{t}$ at period $t$ ) increase, denoted Pr. More importantly, this information in $\operatorname{Pr}$ is over and above that contained in $\mathrm{E}_{\mathrm{t}-1}$ (earnings at period $\mathrm{t}-1^{9}$ ).

## Concluding Remarks

The OP analysis raises two issues:
$\checkmark \quad$ First, there is no theory to explain the role of annual financial statement numbers in predicting future earnings. How is it that nonearning numbers information is useful for predicting future earnings changes? What is the economic rationale for the nonearning numbers being identified? Why OP use individual ratios while Ohlson argues that it is the aggregated total assets variable that should be used?

These questions are dealt with in chapters 3 and 4. A possible explanation for why the nonearning numbers information is useful for predicting future earnings changes might relate to the economics of the firm. Consider the U.K. economy in recent years. Manufacturers are complaining that stocks are rising because consumers are failing to purchase goods i.e changes in stocks may contain information about future sales (and therefore profits). This means that the balance sheet may contain information about the

[^11]persistence of current earnings. Research and Development may be a signal about future excess profits. In a market where product differentiation is important (chemicals, cars), research and development may be a way to identify companies which are developing their products. Thus the balance sheet contains information about future excess profits.
$\checkmark$ Second, OP find that financial statement numbers information is not impounded in prices as soon as the financial statements [FS] are made public i.e excess returns can be made using trading strategy based on previous FS numbers. Why is it that the information is only impounded when the earnings are realised? Why is there lagged impounding? Why is there a difference between the information captured by $\operatorname{Pr}$ and the information set captured by $\mathrm{P}_{\mathrm{t}-1}$ ? OP test for risk and size but still the answer is not known ${ }^{10}$.

Chapters 5,6 , and 7 provide the answer to the above issue. The explanations of why the financial statement information is not impounded in current prices but in the following year's stock returns are, first, that financial statements capture the "temporary" changes in current earnings and not the "permanent" changes and thus the market consider unworthy in terms of costs and time looking for this lagged impounding effect in the financial statements. In other words, the ability of the accounting descriptors to contain information about future earnings changes is timespecific; second, the lagged impounding phenomenon is not valid for a particular distribution of the financial ratios, that is, negative and/or positive values. Third, large firms' information of the financial statement reports, concerning future earnings changes, is reflected in next period's return, while the information of small firms is impounded in the current year's return.

[^12]
### 2.4 THE DATA

Published annual accounting data available from DATASTREAM ${ }^{11}$ and EXSTAT databases, for the period 1980-88, are used. Datastream is mainly used but where information is not available or missing from datastream, data from exstat are used to complete the data set.

However, special formulas are used by Datastream to calculate ratios while data in exstat are recorded as appeared in the financial statements. In order to avoid having any discrepancies in the way ratios are calculated, the data extracted from Exstat are treated with the same formulas as used by Datastream.

Two industries, Stores and Chemical, are examined: [1] across industry and over time; [2] pooled over firms and time.

## Industry Classification

An important assumption of industry ratio analysis is that significant differences in the distributions of industry ratios exist. Greig (1992) explores an alternative interpretation of the Ou and Penman (1989a) result based on the above assumption. More fundamentally, Greig suggests that variations in the risk and other economic characteristics between different industries may account abnormal returns. Since the distribution of the descriptors will vary according to industry, the Pr summary measure may capture industry specific characteristics [Greig (1992), p. 415]. Consequently, when these summary measures are used to take long and short ross industries means that Pr measure is sorting in part on industry rather than the future earnings signal inherent in the accounting data.

In order to assess whether the OP results might be driven by variations across different industries, I perform the analysis for two different industry sectors, stores and chemicals. These are chosen because of their distinctive economic characteristics;

[^13]the stores industry is largely driven by high volume in a low margin business with homogeneous products and little in way of research and development. The chemical industry, by contrast, is more oligopolistic and undertakes significant research and development. The sample of the Stores industry is comprised of 40 companies of which 15 are found on the FTSE100 index; the CHEMICAL industry is comprised of 29 companies of which 10 are found on the FTSE100 index.

From the 68 ratios used by OP (1989) paper only 51 have been used either because of the
$\checkmark$ non-availability of data;
$\nabla$ different definitions used from that of Ou and Penman;
$\rangle$ a ratio is defined as missing if it has many observations missing.
Some of the accounting ratios which are not considered due to the non-availability of data are replaced by some other ratios which believed to give similar information. For example, in the place of research and development, capital expenditure is used instead. The overall number of ratios used increases to 83 , considering the $\Delta \Delta$ and $\% \_\Delta^{12}$ of the accounting descriptors considered.

## The classification of financial ratios

In Chapter 3, the financial statement analysis carried for U.K. data over the period 1980-88, for both industries Stores and Chemical, is presented. Financial statement analysis embraces a number of ratios to evaluate the financial aspects, e.g risk, return, liquidity etc.

Ratios entail the division of one or more items on the financial statements by another related item or items and have been recognised as useful indicators of financial performance and are routinely computed and published by financial analysis firms. These ratios become "benchmarks" against which to compare a firm's results to evaluate its effectiveness.

More than 30 different ratios or variations of ratios have been discussed in the

[^14]financial analysis literature and therefore, it is thought appropriate, to present here, first how the ratios used by Ou and Penman (1989) might be classified and compare these ratios with the ratios used in chapter's 3 financial statement analysis. However, it should be noted that OP do not classified the ratios.

The intended use of each ratio is discussed (although, a fuller interpretation is provided in chapter 3) while the calculation of the ratios as supplied by Datastream is discussed briefly in the next section. Ou and Penman ratios might be classified into five groups:
$\checkmark$ Profitability and Return
$\bigcirc$ Long-term Solvency and Stability
$\Delta$ Short-term Solvency and Liquidity
$\checkmark$ Efficiency
$\diamond$ Shareholders' Investment Ratios

## Profitability and return

Profitability ratios are designed for the evaluation of the firm's operational performance. The ratios yield an indicator of the firm's efficiency in using the capital committed by stockholders and lenders.

## Return on opening/closing equity

Return on equity signifies the percentage rate of return on shareholders' funds. It measures the efficiency with which common shareholders' equity is being employed within the firm. Regardless of a company's total liability and capital employed, this ratio compares the company's net profit solely with the owner's investment.

## Return on total assets

Return on total assets ratio indicates the company's efficiency/industry in the use of its economic resources. The return on total assets of a company will get higher as the assets become older because the denominator will decrease each year due to the increase in accumulated depreciation. Second, in case of price increases due to
inflation will result in a company using recently purchased assets showing a relatively lower return on these assets.

## Depreciation/fixed assets

The depreciation to fixed assets ratio indicates whether the return on the assets gets higher because of the age of the assets, because as the assets become older the denominator will decrease due to increase in accumulated depreciation.

## Gross margin ratio

The gross margin ratio is merely a firm's gross profit expressed as a percent of sales. It helps management to measure the operational efficiency of production and sales as a change or difference in gross profit ratio can signal
$\rangle$ differing selling prices - raised or discounting;
$\checkmark$ different product costs, which may or may not indicate different quality.

## Operating profit to sales

The operating profit to sales ratio is simply the firm's net income expressed as a percent of sales. It indicates the final result of management's profit directed activities.

## Pretax income to sales

The pretax income to sales ratio indicates how much of the income before tax is earned from each dollar of sales.

## Net Profit Margin

The net profit margin represents the average profit margin received by a company on sales.

## Long-term solvency and stability

The main objective of long-term solvency is to indicate the firm's ability to meet both the principal and interest payments on long-term obligations. These measures stress the long-run financial and operating structure of the firm.

## Debt/Equity ratio

The debt to equity ratio indicates a company's capital structure. It indicates whether a company is highly geared (debt) or not. The more highly geared a company, the higher the risk that little will be available to distribute by way of dividend to the ordinary shareholders. The reason being debt carries a fixed rate of interest (or fixed rate of dividend if in the form of preference shares) and a given(large) amount must be paid out from profits to holders of debt before arriving at a residue available for distribution to the holders of equity.

## Long-term debt to equity

The long-term debt is concerned with a company's long-term structure. A company consists of fixed assets and net current assets e.g. working capital. These assets must be financed by long-term capital of the company which is either share capital and reserves or long-term debt capital i.e creditors falling due more than one year.

## Times Interest earned

The times interest earned shows whether the company has enough profits before interest and tax to pay its interest costs comfortably, or whether its interest costs are high in relation to the size of its profits, so that a fall in PBIT(profit before interest and tax) would then have a significant effect on profits available for ordinary shareholders.

## Repayment of LT debt as \% of total LT debt

The repayment of Lt debt as $\%$ of total LT debt indicates to the long-term lender how secure are the interest payments.

## Issuance of LT debt as \% of total LT debt

The issuance of LT debt as \% of total LT debt indicates whether the company is highly geared or not - a company having large proportion of borrowings is "highly geared" whereas a company financed predominantly by shareholders' funds or equity has "low gearing".

## Cash Flow to total debt

It is the ratio of a company's net cash flow to its total debt. Obviously, a company needs to be earning enough cash from operations to be able to meet its foreseeable debts and future commitments and the cash flow and changes in cash flow ratio provide a useful indicator of a company's cash position.

## Short-term solvency and liquidity

Neither profitability nor gearing addresses directly the key of liquidity and the general objective of short-term solvency(liquidity) ratios is to indicate the firm's ability to meet its short-term financial obligations.

## Current Ratio

The current ratio is the "standard" test of liquidity. The idea behind this ratio is that a company should have enough current assets that give a promise of "cash to come" to meet its future commitments to pay off its current liabilities.

## Quick Ratio

However, not all companies are able to convert all their current assets into cash very quickly. In particular, for example, some manufacturing companies might hold large quantities of raw materials stocks which must be used in production to create finished goods stocks. Finished goods stocks might be warehoused for a long time or sold on lengthy credit. In such businesses, where stock turnover is slow, most stocks are not very "liquid assets" because the cash cycle is so long. For these reasons, an additional liquidity ratio, known as quick or acid test ratio, is calculated.

## Change in total uses of funds/Change in sources of funds/Change in funds

A company can obtain liquid assets from sources other than sales, such as the issue of shares for cash, a new loan or the sale of fixed assets. But a company cannot rely on these at all times and in general, obtaining liquid funds depends on making sales and profits. Even so, profits do not always lead to increases in liquidity. This is mainly because funds generated from trading may be immediately invested in fixed assets or paid out as dividends. A useful ratio derived from the funds statements is $\checkmark$ funds generated from operation/total sources of funds

## Efficiency

Efficiency ratios usually consist of the sales figure in the numerator and the balance of an asset, for example, inventory, accounts receivable, in the denominator. The objective is to indicate various aspects of operational efficiency.

## Inventory Turnover

The inventory control revolves around the delicate balance of not wanting to maintain too much or too little stock at any one time. Obviously, a company wants to maintain sufficient stock and raw materials to ensure continual steady production and the ability to meet customer requirements. Conversely, the stock levels must be at such a level to minimise costs, for example, storage costs.

## Days sales in accounts receivables

The days sales in accounts receivables represents the average time it takes debtors to actually pay for purchases. Collection period is a good credit control indicator because it shows how quickly a company receives cash from its debtors, therefore improving company liquidity, asset turnover and ultimately return on capital employed.

## Sales/total assets

The sales to total assets ratio indicates the degree of achievement of generating revenue from the firm's assets. To use gross sales would result in including some
revenues not actually earned i.e some subsequently "cancelled" by sales returns or reduced by sales discounts.

## Sales/working capital

The sales to working capital ratio indicates how much working capital is needed to finance sales over and above that capital invested in fixed assets. It is unwise to set target levels for working capital turnover as it is the direct result of maintaining optimum levels for each of the underlying net current assets items. If this ratio is subject to an upward trend, then this suggests overtrading, which means sales are increasing without adequate capital to support them and vice versa.

## Sales/fixed assets

The sales to fixed assets represents the utilisation of fixed assets or those sales produced by the available fixed assets. As a rule, it indicates the efficiency in the use of fixed assets and an improvement in this ratio should mirror by an eventual improvement in the return on capital employed.

## Sales/cash

The sales to cash ratio depends on each individual company's cash management policy.

## Working capital/total assets

A company that has large volume of stocks and debtors might be over-investing in working capital and so tying up more funds in the business than it needs to. This would suggests poor management of debtors(credit) or stocks by the company.

## Shareholders' investment ratios

Ratios helping equity shareholders and other investors to assess the value and quality of an investment in the ordinary shares of a company.

## Change in dividend per share

The dividend per share indicates the fixed rate of interest in pence received by and it is clearly an item of some interest to shareholders.

## Cash dividends as \% of cash flows

In the financial statement analysis carried out in chapter 3, similar ratios to the ones OP (1989) are employed. A comparison of the financial ratios used in the OP (1989) paper and in this thesis is illustrated in the following table:

Table 2.1: A comparison of the ratios used in the OP analysis with the ratios used in this study.

## Ratios used by OP

This study

| Current ratio | yes |

## Formulas for the calculation of ratios used in this study

There is no general agreement about the precise definitions (formulas) for the calculation of ratios. Also, sometimes the way an accounting ratio is defined might alter the empirical results. For example, Greig (1992) attempts to use exactly the same definition of variables on the same data set OP (1989a) use, but obtains very different results. Greig attributes this to a slightly different definition of an accounting descriptor. In order to avoid the problem in this study, the ratios based on accounting variables definitions in Datastream are defined as follows [the Datastream number is included in brackets]

| Current ratio: | current assets[376]/current liabiliti |
| :---: | :---: |
| Quick ratio: | total current assets[376] - total stock and work in progress[364]/total current liabilities[389] |
| Days sales in accs receivables: | total stock and work in progress[364]/total sales[104] * 365 |
| inventory turnover: | total sales[104]/total stock and work in progress[364] |
| inventory/total assets: | total stock and work in progress[364]/work in progress + debtors[367] + cash and equivalent and any other current asset[375] + total fixed |
|  | assets(gross)[330] - depreciation of fixed assets[338] |
| total sales: | domestic sales[101] + exports[102] + overseas sales[103] - inter company sales[108] + associate |
|  | company sales[109] + value added taxgross[123] + other duties and taxes[125] |
| depreciation: | provisions for amount written off[818] and depreciation of fixed assets and assets leased in[334]. |
| dividend per share: | figures are adjusted for subsequent scrip and rights issue[190] |
| return on opening equity: | earned for ordinary-full tax or earned for ordinary-adjusted / equity capital and reserves total intangibles + [total deferred tax or deferred tax] |
| capital expenditure: | capital expenditure contracted[292] |
| debt/equity: | trade debtors[287] + instalment credit[368] + due |
|  | from associates and unconsolidated |
|  | subsidiaries[660] + HP creditors + taxati |

| total uses of funds: | total of funds used and the movements In <br> working capital[460] <br> total funds generated from operations[405] + <br> funds raised by capital issues[411] + funds |
| :--- | :--- |
| total sources of funds: | raised from other sources[426] <br> pre-tax profits[400] + depreciation[402]+ other <br> adjustments[404] + special provisions[591] + <br> amortisation of intangibles[975] |

### 2.5 ESTIMATION ISSUES USING RATIOS

A number of practical problems when carrying out a ratio analysis have to be faced. The problems are various:

Ratio Selection: A logical relationship between the numerator and denominator must exist and the ratios must be formed only by elements based on common values. Analysts must have in mind what they want to get from each ratio.

Negative numbers: existence of negative numbers can be problematical when transforming the original data to approximate better to a normal distribution. Certain transformations such as logs are impossible for negative numbers and others potentially misleading.

The option an analyst has when facing negative numbers are:
$\nabla$ delete the observation from the sample;
$\checkmark$ examine reasons for the negative denominators and make subsequent adjustments;
$\checkmark$ use an alternative ratio capturing similar aspects.

## Extreme/Outlier observation

An outlier is an observation appearing to be inconsistent with the remainder of that set of data. To decide whether an observation is an outlier a useful first step is to determine whether the outlier arises due to computation reasons.
$\Delta$ is the extreme value due to a recording error? Compare the numbers in the computation of the financial ratio with the numbers in the annual reports. $\Delta$ is the extreme value due to the denominator of the ratio approaching zero in a particular year? Values of prior years can provide useful evidence in deciding if this situation exists.

A useful second step is to examine the accounting classification, the accounting methods and the economic and structural change as reasons for the extreme
observations.
An analyst when faced with outliers not caused by recording errors can $\delta$ delete the outlier on the grounds it represents a " true outlier". $\Delta$ retain the outlier on the grounds it represents an extreme state of the underlying characteristic.
$\Delta$ making adjustments for the economic or accounting factors that cause the outlier.
$\checkmark$ "winsorising" the sample, for example, changing the value of the extreme observation to the value of the nearest observation not viewed as "suspect". $\checkmark$ "trimming" the sample by deleting the top N and the bottom N observations.

Unavailable data: financial reports are often severely delayed and financial information regarding unquoted companies may not included on available databases. In addition, large organisations with a wide range of activities in different industries may not present completely segmental information and therefore, a comparison with other firms of interest may not be feasible.

## Normality

Much of the analysis of the distribution of financial ratios focuses on the normal distribution. If normality is rejected, the options available are the following:
$\bigcirc$ impose normality on the data. This can be achieved by ranking all the observation in the data examined and then converting these ranks to points on a standardised normal distribution:
$\checkmark$ attempt to transform data such that a normal distribution assumption is descriptive;
$\checkmark$ attempt to impose normality by deleting observations that deviate most from normality;
0 attempt to impose normality by resetting extreme observations to less extreme values;
$\diamond$ recognise non-normality without attempting to identify the specific non-
normal distribution;
$\rangle$ winsorising or trimming impose normality.
Ezzamel, Molinero and Beecher identify that even after removing the outlier many distributions still appear to be non-normal. On the basis of this they conclude that nonproportionality is the reason why normality could not be achieved. Deakin (1976), for U.S manufacturing firms over 1953-73 and other in U.S.A, tests the normality assumption. Deakin concludes that the normality assumption was untenable for 11 well-known ratios, except for the debt/total asset ratio. If, however, normal distribution is not valid for the data examined then [a] impose normality on the data; [b] seek a more suitable ratio model. Concerning the former, the traditional approach is to transform the data so it eventually conforms. Frecka and Hopwood (1983) use Deakin's original ratios and find that by deleting outliers normality could be achieved for most ratios of the manufacturing firms and specific industry groupings. This also greatly reduces variances and increases their stability over time (skewness and Kurtosis measures are used). Concerning the alternative (retaining their information by using a suitable ratio model) advances have been made by McLeay (1986a). He looks at the theoretical models of distribution and making certain assumptions found that they fitted his data from French companies. Bougen and Drury (1980) for U.K data concludes that nonnormality exists because of the existence of extreme observations and the differing levels of skewness. Buckmaster and Saniga (1984) conclude that "the current ratio has a J-shape distribution" rather than the conclusion of most prior research that the current ratio does "not have a normal distribution".

A high degree of correlation among financial ratios of a given firm can be expected since [a] many ratios have common components; [b] some financial statement items tend to move in the same direction as other items. This expectation was confirmed by the somewhat scanty evidence available e.g short-term liquidity ratios in a sample of petroleum and steel firms were found to be highly correlated. This evidence is consistent with a smaller set of ratios being able to capture much of the information contained in the numerous financial ratios that can be calculated.

Ratio distribution tend to be correlated over time for [a] firms set and attempt
to maintain optimal ratio levels relative to some industry target e.g industry mean; [b] industry and economy-wide events affecting all firms within an industry.

### 2.6 CONCLUDING REMARKS

This chapter explains how the different hypotheses in the following chapters are developed and defines the accounting descriptors used in the empirical tests. It draws attention on the sensitivity of the results to different accounting descriptors' definitions and the problems faced when carrying out a ratio analysis.

CHAPTER THREE
Do The Annual Financial Statement Report Numbers Contain Information About Future Earnings Changes?

Evidence For The U.K.

### 3.1 INTRODUCTION

The primary purpose of this chapter is to examine whether annual financial statement report numbers might capture those attributes of firms which reflect some regularity in the earnings generating process. Specifically, an investigation is made whether annual financial statement numbers convey information about earnings changes one period ahead, which is not reflected in current earnings ${ }^{1}$.

This research tests whether the U.K. financial statement numbers exhibit information about future earnings changes during the period 1980-88. In addition, the sign of the estimated coefficients is compared with the OP estimated coefficients, in order to examine whether the same relationships exist for the U.K., as for the U.S.A, between the accounting descriptors and the future earnings changes.

This is important since Greig (1992), despite using the models reported by OP (1989a) and the COMPUSTAT variables definitions supplied by Penman in correspondence, finds that the distribution of the $\mathrm{Pr}_{\mathrm{it}}{ }^{2}$ values is skewed towards the lower $\operatorname{Pr}_{\mathrm{it}}$ values: $40.9 \%$ of the observations are in the $\operatorname{Pr}_{\mathrm{it}}>0.6$ portfolios and $17.1 \%$ in the $\operatorname{Pr}<0.4$ portfolio. The comparable numbers for OP are $45.7 \%$ and $10.3 \%$ respectively. Greig(1992) argues as an explanation for this difference in $\operatorname{Pr}_{\mathrm{it}}$ distribution "a possibility is an unknown difference in defining, one or more of the accounting variables".

The information perspective of accounting implies that the contemporaneous association between financial statement accounting numbers and stock returns can be viewed as resulting from a predictive information link between these accounting numbers and some unobservable, value-relevant attributes of the firm. Evidence suggests that future earnings are value relevant. The findings of the Ball and Brown (1968), Beaver and Morse (1978) and Beaver, Lambert and Morse (1981) are all consistent with the notion that the stock prices reflect information regarding future

[^15]earnings. Moreover, the efforts made by financial analysts, investors and management seem to indicate that future earnings are value relevant.

Financial statement report numbers may convey predictive information about future earnings for at least two reasons: first, some financial statement numbers may help to identify the "transitory" component of current earnings which does not persist in the long run. Second, financial statement data may reflect managerial decisions that have implications for future earnings.

The chapter is organised as follows: section 3.2 explains the experimental design; section 3.3 presents the empirical results for Stores and Chemical Industries separately and then together; section 3.4 contains the conclusions.

### 3.2 EXPERIMENTAL DESIGN

## Introduction

As in the OP study, earnings changes are predicted with a logit model ${ }^{3}$. The binary model mitigates the estimation problem of outliers, so common in accounting data series, since it specifies that extreme changes in earnings have no greater influence on the model parameter estimates than any other observation.

To identify which accounting descriptors exhibit information about future earnings changes, each descriptor is included as the sole explanatory variable in a univariate logit model. To test the ability of the accounting descriptors to jointly describe one-year ahead future earnings, we include all the descriptors whose estimated coefficients are significant at the 0.10 level in the univariate logit model, in a multivariate logit model. However, since logit analysis throws away information ${ }^{4}$, univariate and stepwise regressions are employed as well. The analysis is carried out for the stores and chemical industries separately and then together. The estimation

[^16]method is cross-section; that is each coefficient is assumed to be constant over the period.

In each logit model, the dependent variable is specified in two ways: first, the distribution of the $\% \Delta$ operating profit earnings is partitioned by the mean; secondly, the distribution is partitioned by the mean of the $\% \Delta$ operating profit, but outliers are deleted from the sample data, to examine whether the ability of the accounting descriptors to describe subsequent earnings changes is caused by the outliers ${ }^{5}$. It has been documented in the segmental reporting literature that financial statements do have information only when there are radical economic changes. In the segmental reporting literature, these economic conditions are described as outliers.

In OP study, a drift is estimated ${ }^{6}$. In this research, no drift is estimated because of the short-time series of the data available. Partitioning by the mean is an attempt to overcome the problem of inflation ${ }^{7}$.

### 3.3 THE OP RESULTS

Ou and Penman (1989) use published accounting data to estimate the probability of one year - ahead earnings increase, labelled Pr , for the eleven years 1973-83. For a given firm-year observation

$$
\begin{equation*}
\hat{P}_{r_{i k}}=\left[1+\exp \left(-\Theta \mathrm{X}_{i t}\right)\right]^{-1} \tag{3.1}
\end{equation*}
$$

where $\mathrm{X}_{\mathrm{it}}=$ set of accounting variables in the annual financial statements, $\Theta=$ set of estimated coefficient weights applied to those variables.

To estimate the coefficients a binary dependent variable specification is used to indicate an increase or decrease in the following year's operating profit.

[^17]Ou and Penman denote the change in earnings for year $\mathrm{t}+1$, as $\Delta \mathrm{EPS}_{\mathrm{it+1}}=\mathrm{EPS}_{\mathrm{it+1}}-\mathrm{EPS}_{\mathrm{it}}-$ drift $_{\mathrm{itt}+1}$. Drift is estimated because earnings increases tend to exceed earnings decreases, in inflationary conditions. In estimating the $\mathrm{Pr}, \mathrm{OP}$ define the earnings as the primary earnings-per-share before extraordinary items. An earnings change is classified as 1 if the $\Delta X_{t+1}$ in EPS exceeds the most recent-four-year average and 0 otherwise. The drift is estimated as the mean earnings per share change over the four years prior to year $t+1$.

OP used annual financial statement data over the periods 1965-72 and over 1973-77 [the drift was estimated during 1961-64 period]. Their analysis was conducted in 3 stages. In the first stage, sixty eight (68) financial statement ratios are selected on the basis of their ability to predict the direction of the annual change in the following year. These accounting ratios which are eligible for inclusion in the final version of the model are determined by running univariate legit on the comprehensive set of 68 accounting ratios and selecting those significant at the $10 \%$ level.

The first model over 1965-72 retains 34 accounting ratios. These 34 variables and their estimated coefficients are used to estimate $\operatorname{Pr}$ for the years 1973-77. The second model over $1973-77$ retains 34 variables and is used to calculate $\operatorname{Pr}$ for the years 1978-83. 34 or $50 \%$ of the coefficient estimates of the 68 ratios, in both periods 1965-72, 1973-77, have p-values less than 0.10. The estimates within each estimation period are not from independent observations, however. The reason being the overlapping between estimation and prediction periods. Of the 34 descriptors with pvalues less than 0.10 in the first period, 32 have the same sign on the estimated coefficient in the second period and of these 32 only 6 did not have $p$-value less than 0.10. Similar consistency is observed for descriptors with p-values less than 0.10 in the second period. This indicates they captured attributes of firms that demonstrate some regularity in generating earnings and that predictive ability will hold up outside of the estimation periods. Ou and Penman distance themselves from rationalising the signs of the coefficient estimates.

In the second stage, to test the ability of the accounting descriptors to jointly describe future earnings changes, OP reduce the set of the 34 retained ratios further. OP include in a multivariate model all ratios whose coefficients are significant at 0.10
level in the univariate analysis. They then drop all variables for which coefficient estimates in the multivariate estimation are not significant at the 0.10 level, leaving 19 variables for 1965-72 and 18 for 1973-77 period.

In the third stage, they investigate each of the remaining variables stepwise deleting descriptors not significant at the 0.10 level. In this stage, 3 descriptors are dropped in the 1965-72 and none in the 1973-77 period. The final models (with 16 descriptors in the first estimation and 18 in the second are summarised below [ Ou and Penman (1989), p. 307, table 3]:

Chapter 3
Do balance sheet numbers contain information about future earnings?

|  | 1965-1972 estimation |  | 1973-1977 estimation |  |
| :---: | :---: | :---: | :---: | :---: |

| Return on opening equity |  |  | -1.9197 | $\begin{aligned} & 44.84 \\ & (0.000) \end{aligned}$ |
| $\Delta$ in return on opening equity |  |  | 0.4124 | $\begin{aligned} & 10.13 \\ & (0.002) \end{aligned}$ |
| \% $\Delta$ in capital expenditure/total assets | -0.0659 | $\begin{aligned} & 9.92 \\ & (0.002) \end{aligned}$ |  |  |
| \% $\Delta$ in capital expenditure/total assets with one year lag | -0.0758 | $\begin{aligned} & 16.10 \\ & (0.000) \end{aligned}$ | -0.0288 | $\begin{aligned} & 4.32 \\ & (0.0334) \end{aligned}$ |
| Debt/equity |  |  | -0.0334 | $\begin{aligned} & 6.84 \\ & (0.009) \end{aligned}$ |
| \% $\Delta$ debtequity | 0.1514 | $\begin{aligned} & 7.25 \\ & (0.007) \end{aligned}$ |  |  |
| $\% \Delta$ in sales/total assets | 0.5754 | $\begin{aligned} & 13.15 \\ & (0.000) \end{aligned}$ |  |  |
| Return on total assets | -4.2089 | $\begin{aligned} & 8.62 \\ & (0.003) \end{aligned}$ | -11.3727 | $\begin{aligned} & 90.95 \\ & (0.00) \end{aligned}$ |
| Return on closing equity | -3.0088 | $\begin{aligned} & 28.97 \\ & (0.000) \end{aligned}$ |  |  |
| Gross margin ratio | 0.8152 | $\begin{aligned} & 23.64 \\ & (0.00) \end{aligned}$ |  |  |
| \% in pretax income/sales |  |  | 0.0141 | $\begin{aligned} & 2.87 \\ & (0.090) \end{aligned}$ |
| sales to total cash |  |  | -0,003 | $\begin{aligned} & 3.81 \\ & (0.051) \end{aligned}$ |
| \% $\boldsymbol{\Delta}$ total assets |  |  | -0.9628 | $\begin{aligned} & 37.19 \\ & (0.000) \end{aligned}$ |
| Cash flow to debt | 0.3282 | $\begin{aligned} & 3.47 \\ & (0.062) \end{aligned}$ |  |  |
| Working capital/total assets |  |  | 0.9571 | $\begin{aligned} & 28.39 \\ & (0.000) \end{aligned}$ |
| Operating income/total assets | -0.2726 | 4.10 $(0.43)$ | 3.5859 | $\begin{aligned} & 43.76 \\ & (0.000) \end{aligned}$ |
| Repayment of LT debt as \% of total LTdebt | 0.5079 | $\begin{aligned} & 24.35 \\ & (0.000) \end{aligned}$ | 0.0576 | $\begin{aligned} & 3.87 \\ & (0.49) \end{aligned}$ |
| Cash dividend/cash flows | 2.4112 | $\begin{aligned} & 159.01 \\ & (0.000) \end{aligned}$ |  |  |
| Intercept | 0.5162 | $\begin{aligned} & 95.57 \\ & (0.000) \end{aligned}$ | 0.7416 | $\begin{aligned} & 104.28 \\ & (0.000) \end{aligned}$ |

The various test statistics indicate significant ability of the descriptors to jointly describe subsequent earnings changes. At first glance, there does not appear to be much consistency in the descriptors included in the models for the two periods. Of the 28 descriptors in either period, only 6 appear in both models. However, these are multivariate models and the inclusion of a particular variable and the sign on its estimated coefficient will depend on variables already in the model at the relevant step in the step-wise procedure. Moreover, many of the descriptors capture similar operating characteristics. For example, inventory, sales, etc., appear in more than one descriptor.

The six descriptors that appear in both models are
$\Delta \Delta$ dividend per share;
$\checkmark$ \% change in capital expenditures/total assets with one year lag;
$\rangle$ return on total assets;
$\checkmark$ operating income/total assets;
$\rangle$ repayment of LT debt as \% of total LT debt intercept. and the intercept.

### 3.4 THE RESULTS OF THIS RESEARCH

In order to assess whether the OP results might be driven by variations across different industries, an analysis is performed for two different industry sectors, stores and chemicals, first separately and then together.

## Stores Industry

## Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit

## Univariate Logit Analysis

To determine which accounting descriptors predict the direction of future earnings
changes in the following year, each descriptor is included as the sole explanatory variable in a univariate LOGIT earnings change prediction model. The appendix to this chapter, table A1 presents the coefficient estimates for stores industry for all 83 accounting descriptors for the period 1980-88, along with a $t$-statistic (and p-value) relevant for the hypothesis that the coefficient is zero. During the period 1980-88, twenty (20) accounting descriptors coefficients are significant at the 0.10 level [have p-value less than 0.10 ] and in a second stage, are included in the multivariate analysis. While Ou and Penman distance themselves from the data, so as not to develop "stories" that rationalize the signs of the coefficients estimates, I do not. I attempt to give a plausible explanation for the results. However, this may not be the only possible explanation; that is, the analysis here is indicative.

Table 3.1: Stores Industry Comparison between OP's study with this research's accounting variables coefficients signs examining their relationship with the \% $\Delta$ in operating profit.

| Accounting Descriptors | Ou and Penman accounting coefficient 1965-72 1973-77 |  | This research's accounting coefficient 1980-88 |
| :---: | :---: | :---: | :---: |

| total income/cash flow | -0.0073 | -0.0019 | -0.46940 |

## Rationalization of the coefficients signs (analysis is indicative)

The financial descriptors exhibiting information about future earnings can be grouped into liquidity and efficiency, profitability, long-term solvency and stability ratios.

## Liquidity and Efficiency

The current ratio, the $\% \Delta$ in current ratio, the $\Delta$ in sales/working capital, the $\Delta$ in inventory turnover, the inventory, the $\Delta$ in inventory and the $\% \Delta$ in sales fall into the liquidity and efficiency group:

## Current ratio, $\Delta$ current ratio and $\% \Delta$ current ratio

OP report a positive relationship for the years 1965-72 while a negative relationship for the years 1973-77. In this study, the current ratio, $\Delta$ and the $\% \Delta$ current ratio have a negative coefficient while $\% \Delta$ operating profit has a positive coefficient during the 1980-88 period.

The decrease in the $\Delta$ and $\% \Delta$ in current ratio might be attributed to the fact that the stores industry might invest profits from trading in fixed assets or to profits being paid out as dividends. Thus an increase in profits does not necessarily lead to an increase in liquidity. This conclusion is further supported by negative relationship the cash flow/total debt ratio also exhibits with the $\% \Delta$ in operating profit and the positive relationship the depreciation/fixed assets exhibits with the $\% \Delta$ in operating profit.

## Depreciation/Fixed Assets

OP report a positive coefficient. In this study, there also exists a positive relationship between depreciation to fixed assets and $\% \Delta$ operating profit during 1980-88. This might be attributed to an increase of investment in fixed assets [dealing with stores industry] in the early years of the assets age, for example the opening of a new shop or to the accumulated depreciation increase when the assets age gets larger and larger.

## $\Delta$ inventory turnover

OP use $\% \Delta$ inventory turnover in their analysis. In this study, the $\Delta$ inventory turnover exhibits a negative relationship with $\% \Delta$ operating profit. However, $\Delta$ inventory ratio does not account for the sales variable and therefore, we cannot draw any conclusion about the company's position.

## $\% \Delta$ sales

OP report a negative coefficient. In this study, the $\% \Delta$ sales is also negatively related with $\% \Delta$ operating profit. However, this ratio does not account for the cost of the goods sold, and it might refer to firms financing their working capital requirements through debt.

## $\Delta$ Sales/Working Capital and \% $\Delta$ sales/working capital

OP report a negative coefficient. A positive relationship is found for the U.K. data. The $\Delta$ sales/working capital and $\% \Delta$ sales/working capital give the additional information missing from the $\Delta$ inventory turnover and $\% \Delta$ sales variables. The $\Delta$ and $\% \Delta$ sales/working take account both of the sales and the working capital requirements.

- Profitability

The return on opening equity, the $\Delta$ and the $\% \Delta$ in return on opening equity, the operating profit/sales, the return on closing equity, the return on total assets and the net profit margin ratios fall into the profitability group:

Return on opening equity, $\Delta$ return to opening equity and $\% \Delta$ return to opening equity
Ou and Penman report negative coefficient. In this study, these return accounting descriptors exhibit a negative relationship with $\% \Delta$ operating profit variable. This might be attributed to the fact that the industry might have generated a lot of sales by keeping prices down and accepting low profit margin per $£ 1$ of sales. It reveals
economic rationale.

## Operating profit to sales

The operating profit to sales variable has a negative coefficient while the $\% \Delta$ in operating profit has a positive coefficient. This might be explained by the fact that the industry might have had to boost sales by keeping prices low and therefore accepting low profit margin per $£ 1$ sales. Ou and Penman report a negative sign.

## Net Profit Margin

The net profit margin has a negative coefficient while the $\% \Delta$ in operating profit has a positive coefficient. Low margin might be due to new product launching or a management decision to increase their number of customers and ultimately market shares by pulling prices down. Ou and Penman report a negative sign.

## Return on total assets

The return on total assets ratio has a negative coefficient while the $\% \Delta$ in operating profit has a positive coefficient. This suggests that the industry has difficulties in its assets generating sales. This might be attributed to the fact that the industry might have generated sales by keeping prices down and accepting low profit margin per $£ 1$ of sales because of recession in the market. Ou and Penman report a negative relationship as well.

## - Long term solvency and stability

The income to cash flow, the debt to equity, the times interest earned and the cash flow to debt ratio fall under long term solvency and stability category.

## Income to Cash Flow(total cash flow to total debts) and cash flow to total debt

Ou and Penman report a negative sign. Income to cash flow exhibits a negative relationship with $\% \Delta$ operating profit for the U.K. This might be attributed to decrease in long term debt. The industry does not seem to be high geared.

## Times Interest Earned

Ou and Penman report a positive coefficient. Times interest earned exhibits a negative relationship with $\% \Delta$ operating profit variable. This indicates that the industry is not highly geared.

## Debt/Equity

Ou and Penman report a negative coefficient. A negative relationship is reported in this study as well. However, it should have been a positive relationship in order to give the same signal like the times interest earned ratio and the income to cash flow ratio that the industry is not highly geared. The explanation for the negative relationship exhibited might lie in the reason that the debt/equity might not capture permanent changes.

However, it must be noticed that many of the accounting descriptors capture similar operating characteristics. For example, sales, inventory appear in more than one descriptor.

## Multinomial Logit Analysis

In order to test the ability of the 20 retained accounting descriptors [whose coefficients are significant at the 0.10 level in the univariate logit model] to jointly describe subsequent future earnings changes, we run a multivariate model. All descriptors whose coefficients in the multivariate estimation are not significant at the 0.10 level are also identified in table 3.2.

Table 3.2: Multinomial Logit Estimation For The Stores Industry Examining Whether The Accounting Descriptors Selected Jointly Describe Future Earnings Changes For The Period 1980-88.

| Accounting descriptors | accounting coefficient | Standard Error | t-ratio | problti> $=x$ |
| :---: | :---: | :---: | :---: | :---: |

| total income/cash flow | -0.38890 | 0.2270 | -1.713* | 0.08668 |

* The $p$-values of the $t$-statistic are all significant at the 0.10 level.

In the multinomial analysis, over the period $1980-88$, the $\% \Delta$ in current ratio, the $\Delta$ in inventory turnover, the operating profit/sales ratio and the total income/cash flow ratio contain information for the direction of future earnings' changes. All accounting descriptors belong to different ratio groups. For example, the current ratio belongs to liquidity group, the $\Delta$ inventory turnover to the efficiency group, total income/cash flow to the leverage group while the operating profit/sales to the profitability group. Noteworthy is that the " $\Delta$ inventory turnover" variable is also reported by OP to contain information about future earnings in the period 1965-72.

## Binary specification $(0,1)$ is formed based on the mean of $\% \Delta$ operating profit with outliers being deleted.

## Univariate Logit Analysis

For this alternative method, we examine whether the ability of the accounting descriptors to contain future earnings changes is caused by outliers ${ }^{8}$. For example, the

[^18]inclusion in net income of a large write-down for a plant closing is an outlier. The appendix to this chapter, table AIa presents the coefficient estimates for stores industry for all 83 accounting descriptors for the period 1980-88, along with a t-statistic (and p -value) relevant for the hypothesis that the coefficient is zero. During the period 1980-88, the accounting descriptors which have p-value less than 0.10 and are also found in the first univariate logit method, where outliers are not deleted, are the $\% \Delta$ in current ratio, inventory, times interest earned and return on total assets. The findings suggest that some financial statement numbers' ability to contain information about future earnings is not due to outliers.

Tests of whether the ability of the accounting descriptors might be due to outliers are also presented in the univariate regression estimation.

## Multinomial Logit Analysis

To test whether the accounting descriptors [whose coefficients are significant at the 0.10 level in the univariate logit analysis] jointly describe future earnings changes even when outliers are deleted, we carry out a multivariate analysis. In the multivariate analysis in table 3.3, the accounting descriptors which still exhibit information about future earnings changes are the $\Delta$ current ratio and the sales/working capital variables. The $\Delta$ current ratio variable is found to appear in the multinomial model of both methods (first, where outliers are included and second where outliers are deleted from the sample].

Table 3.3: Multinomial Logit Estimation For The Stores industry Examining Whether The Accounting Descriptors Selected Jointly Describe Future Earnings Changes For The Period 1980-88.

| Accounting Descriptors | Coefficient | Standard Error | t-statistic | prob\|t|>=x |
| :--- | :--- | :--- | :--- | :--- |
| debtors ratio | 21.218 | 45.67 | 0.749 | 0.36378 |
| $\% \Delta$ net profit margin | $0.14504 \mathrm{E}-03$ | $0.2237 \mathrm{E}-03$ | 0.789 | 0.45221 |
| cash flow/total debt | $0.60123 \mathrm{E}-03$ | $0.2546 \mathrm{E}-03$ | 1.471 | 0.15465 |
| sales | $-0.99924 \mathrm{E}-03$ | $0.54578-03$ | -1.709 | 0.08748 |

Once univariate and multinomial logit estimations are carried out, OP investigate the remaining variables step-wise deleting descriptors not significant at the 0.10 level. We
carry, instead, out univariate and stepwise regression estimations for all 83 accounting variables.

## Regression Analysis

## Univariate Regression Analysis

To further test first, whether with no outliers results change and second, whether accounting descriptors can predict the size of the $\% \Delta$ operating profit or just the sign, each descriptor is included as the sole explanatory variable in a regression earnings model and outliers observations are deleted from the $\% \Delta$ operating profit variable.

The accounting descriptors which contain information about future earnings are the $\Delta$ inventory turnover, return on closing equity, the $\Delta$ return on closing equity, the working capital/total assets and the $\Delta$ in working capital/total assets variables [see appendix to this chapter table Alc]. It is noteworthy, that the $\Delta$ in inventory/turnover is reported in OP results as one of the six descriptors which contain future earnings. However, none of these accounting descriptors are found to contain information about future earnings changes in the univariate logit estimations. This might be attributed to the different methodologies used.

## Stepwise Regressions

To test whether the accounting descriptors jointly describe future earnings changes even when outliers are deleted and whether the accounting descriptors can jointly predict the size of the $\% \Delta$ operating profit or just the sign, the $\% \Delta$ of all the accounting descriptors considered are included in the stepwise regression. In the period 1965-72, OP results suggest that the $\% \Delta$ in inventory turnover, $\% \Delta$ in capital expenditure/total assets, are among the six accounting descriptors, which indicate significant ability to jointly describe subsequent earnings changes. In this study, the stepwise regression table 3.4 shows that the two variables mentioned in OP study, the $\% \Delta$ in capital expenditure/total assets and the $\% \Delta$ in inventory/turnover exhibit
significant ability to jointly describe subsequent earnings changes for the U.K data. Apart from the two variables already mentioned, the $\% \Delta$ in inventory and the $\% \Delta$ in sales/cash also jointly describe subsequent earnings changes for the U.K data.

Table 3.4: Stepwise Regression Analysis For The Stores Industry Examining Whether The \% $\Delta$ Of The Accounting Descriptors Jointly Describe Future Earnings Changes For The Period 1980-88.

| Accounting Variable | Coefficient | Standard Error | t-ratio | Problts=x |
| :---: | :---: | :---: | :---: | :---: |
| \% C capital expenditureftotal assets | $0.30814 \mathrm{E}-01$ | 0.7171E-02 | 4.297* | 0.00004 |
| \% $\Delta$ sales/cash | $0.24721 \mathrm{E}-01$ | 0.7615E-02 | 3.246* | 0.00156 |
| \% inventory/turnover $^{\text {a }}$ | 1.7502 | 0.4662 | 3.754* | 0.00028 |
| \% $\Delta$ inventory | 1.1530 | 0.4675 | 2.466* | 0.01525 |

## Concluding Remarks

The findings, via logit, suggest that some financial statement report numbers exhibit information concerning the direction of one - year ahead earnings changes. However, the predictive ability of some of these financial statement numbers disappears once outliers are deleted from the sample. Only three accounting descriptors exhibit predictive ability of future earnings changes even when outliers are deleted. These accounting descriptors are the $\% \Delta$ current ratio, inventory and times interest earned variables.

To further test whether the predictive ability of some accounting descriptors about future earnings changes is due to outliers and further whether the accounting descriptors can predict the size of the $\% \Delta$ operating profit and not just the sign, a univariate regression model is run. Different descriptors are found to describe earnings changes one year ahead. It is noteworthy, that the $\Delta$ inventory/turnover variable is found to exhibit information about future earnings changes. The same variable is reported by OP (1989) as one of the accounting descriptors containing information about future earnings changes.

Having examined the stores industry, I examine in the following section the chemical industry. The same tests are also applied here.

## Chemical Industry

## Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit

## Univariate Logit Analysis

To test which accounting descriptors exhibit information about future earnings changes for the chemical industry, each descriptor is included as the sole explanatory variable in univariate logit model. In the univariate logit estimation [see appendix to this chapter table A2a], some of the accounting descriptors describing future earnings changes one year ahead for the chemical industry, are the same descriptors which exhibit information about future earnings changes for the stores industry. Fourteen (14) accounting variables whose coefficient estimates are significant at the 0.10 level are reported. The results are given in table 3.5.

Table 3.5: Chemical Industry
Comparison between Ou and Penman's with this research's accounting variables coefficients sign examining their relationship with the $\% \Delta$ operating profit.

| Accounting Descriptors | Ou and Penman Coefficients <br> $1965-72$ | This research's coefficients <br> 1973-77 | -0.0001 |
| :--- | :--- | :--- | :--- |
| debtors ratio | 0.0001 | 0.02739 |  |
| $\Delta$ debtors ratio | -0.065 | -0.0090 | 0.01979 |
| \% $\Delta$ debtors ratio | -2.929 | -2.9960 | 1.50200 |
| return on opening equity |  | -0.8773 |  |
| $\Delta$ retum on opening equity | -0.036 | -0.4830 |  |
| \% $\Delta$ return on opening equity | -0.024 | -0.3660 | -0.4348 |
| sales/total assets | -6.421 | -6.7617 | -0.8060 |
| return on total assets |  |  | -0.0548 |
| \% $\Delta$ return on total assets | 0.0001 | -0.0008 | -0.4239 |
| sales/fixed assets | -0.469 | -1.1751 | -0.8060 |
| $\Delta$ sales/fixed assets |  | -1.2308 |  |
| \% total assets |  | 1.0217 |  |
| operating profitsales |  | -7.5399 |  |
| sales |  | -0.4239 |  |

## Rationalisation of the accounting coefficients signs ${ }^{9}$ (analysis is indicative)

The sales/total assets ratio, the $\Delta$ net operating profit margin and $\% \Delta$ net operating profit, the operating profit/sales, the $\% \Delta$ sales, the sales/fixed assets, the return on total assets and the return on closing equity, $\Delta$ the return on closing equity and $\% \Delta$ in closing equity variables exhibit same coefficient sign like the stores industry. The accounting descriptors which contain information about the chemical industry and differ in sign from stores industry descriptors are the debtors ratio and the $\% \Delta$ total assets.

## Debtors ratio [average days in accounts receivables]

OP report a positive relationship in the period 1965-72 but a negative one in the period 1973-77. In this study, for the period 1980-88 a positive relationship exists between $\% \Delta$ in operating profit and debtors ratio. This might be due to the industry allowance of generous credit terms to win customers. This ratio indicates the cost of growth.

## \% $\Delta$ in total assets

A positive relationship exists between $\% \Delta$ total assets and $\% \Delta$ operating profit variables. This might be considered as a signal of inside information. The reason being that managers seeing how well a firm is doing, would like the market to know as well and disclose the news to the market through this ratio.

## Multinomial Logit Analysis

To test the ability of the accounting descriptors to jointly describe future earnings changes, I reduce the set of the fourteen (14) retained ratios [whose coefficients are statistically significant in the univariate estimation], by including them, in a

[^19]multivariate model. The results are given in table 3.6.

Table 3.6 Multinomial Logit Estimation For The Chemical Industry Examining Whether The Accounting Descriptors Selected Jointly Describe Future Earnings Changes For The Period 1980-88.

| Accounting Descriptors | Coefficient | Standard Error | t-statistic | problt $>=\boldsymbol{x}$ |
| :--- | :--- | :--- | :--- | :--- |
| Debtors ratio | $0.17409 \mathrm{E}-01$ | $0.6744 \mathrm{E}-02$ | $2.581^{*}$ | 0.00984 |
| $\Delta$ debtors ratio | $0.34805 \mathrm{E}-01$ | $0.2950 \mathrm{E}-01$ | 1.180 | 0.23805 |
| $\Delta \%$ debtors ratio | -2.9098 | 2.518 | -1.156 | 0.24781 |
| Return on opening equity | -0.67929 | 0.2923 | $-2.324^{*}$ | 0.02013 |
| $\Delta$ return on opening equity | -0.19206 | 0.3588 | -0.535 | 0.59247 |
| $\Delta \%$ return on opening equity | -0.47410 | 0.4243 | -1.117 | 0.26386 |
| Sales/total assets | -1.3123 | 0.3570 | $-3.676^{*}$ | 0.00024 |
| Return on total assets | $0.80416 \mathrm{E}-01$ | $0.5349 \mathrm{E}-01$ | 1.503 | 0.13275 |
| $\Delta \%$ return on total assets | $0.35809 \mathrm{E}-01$ | 0.3121 | 0.250 | 0.00230 |
| operating profitsales | $0.23145 \mathrm{E}-01$ | 0.1241 | 0.489 | 0.45600 |
| $\Delta$ net profit margin | 0.78942 | 0.4789 | 0.745 | 0.89600 |
| \%Dtotal assets | 0.96300 | 0.5630 | 0.456 | 0.7912 |

The debtors ratio, the return on opening equity and the sales/total assets accounting variables still contain information about future earnings. The information contained in these three accounting descriptors cannot be attributed to the ratios being within the same category of ratios as all three explain different groups of ratios. The debtors ratio indicates long-term solvency and stability, the return on opening equity indicates profitability and the sales/total assets liquidity and efficiency.

## Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit with outliers being deleted

## Univariate Logit Analysis

In this alternative method, we test whether the ability of the accounting descriptors to describe future earnings changes is caused by the outliers. In the appendix to this chapter, table A2b presents the coefficient estimates for chemical industry for all 83 accounting descriptors for the period 1980-88, along with a $t$-statistic (and p-value) relevant for the hypothesis that the coefficient is zero. The accounting variables having information about future earnings are the debtors ratio, the $\Delta$ debtors ratio, the $\Delta$ sales,
the debt/equity, the $\Delta$ depreciation/fixed assets, the sales/total assets, the $\Delta$ sales/total assets, the $\% \Delta$ sales/total assets and the $\% \Delta$ total assets.
For the chemical industry, the debtors ratio, the $\Delta$ debtors ratio, the sales/total assets and the $\% \Delta$ total assets variables capture information for future earnings and this informational ability is not due to outliers.

## Multinomial Logit Analysis

In the multinomial analysis where outliers are deleted, the accounting descriptors that still contain information about future earnings is the debtors ratio, the $\% \Delta$ capital expenditure, the sales/total assets and the $\% \Delta$ total assets. The debtors ratio, sales/total assets and the $\% \Delta$ total assets capture information about future earnings changes in both binary specification methods used [the first specification with outliers considered and the second specification where outliers are deleted]. Results are presented in table 3.7.

Table 3.7: Multinomial Logit Estimation For The Chemical Industry Examining Whether The Accounting Descriptors Selected Jointly Describe Subsequent Earnings Changes For The Period 1980-88.

| Accounting Descriptors | Accounting Coefficients | Standard Error | t-ratio | probltl $>=x$ |
| :---: | :---: | :---: | :---: | :---: |
| Deblors ralio | $0.14838 \mathrm{E}-01$ | 0.5294E-02 | $2.803^{*}$ | 0.00507 |
| $\Delta$ debtors ratio | 0.55782E-02 | 0.2677E-01 | 0.208 | 0.83491 |
| \% $\Delta$ debtors ratio | -1.8477 | 2.104 | -0.878 | 0.37975 |
| $\Delta$ sales | -0.49853E-06 | 0.2824E-05 | -0.177 | 0.85988 |
| $\Delta$ depreciation/fixed assets | 0.85062 | 1.549 | 0.549 | 0.58282 |
| \% $\Delta$ capital expenditure | -0.12366 | 0.7003E-01 | -1.766* | 0.07743 |
| sales/total assets | -0.81750 | 0.2856 | -2.863 | 0.00420 |
| $\Delta$ sales/total assets | 0.45479 | 1.563 | 0.291 | 0.77103 |
| \% $\Delta$ sales/total assets | -1.2764 | 2.125 | -0.601 | 0.54806 |
| \% tital assets | 2.3374 | 1.205 | 1.940* | 0.05239 |
| $\Delta$ working capital | -0.37206E-05 | $0.4125 \mathrm{E}-05$ | -0.902 | 0.36705 |

Notice that these accounting descriptors capture similar operating characteristics. For example, total assets appear in more than one descriptor.

## Regression Analysis

## Univariate Regression Analysis

To further test whether the ability of some accounting descriptors to predict future earnings changes one year ahead are due to outliers, and whether the accounting descriptors can predict the size of the $\% \Delta$ operating profit or just the sign, a univariate regression model is run [in the appendix to this chapter, see table A2b]. The univariate model captures different accounting descriptors, from the ones reported in the univariate logit model, to exhibit information about future earnings changes. The accounting descriptors which contain information about future earnings changes are the $\Delta$ current ratio, the $\% \Delta$ current ratio, the debtors ratio, the $\% \Delta$ capital expenditure, the sales/total assets, the $\% \Delta$ sales/total assets, the $\% \Delta$ total assets, the $\Delta$ working capital and the $\% \Delta$ working capital. The sales/total assets and the $\% \Delta$ total assets are the accounting descriptors however, which contain information about future earnings in both univariate logit and regression models. For these two accounting descriptors it might be argued that they are indeed revealing information about future earnings and are not just an effect caused by outliers.

## Stepwise Regression Analysis

In the stepwise regression, during the period $1980-88$, the $\% \Delta$ debtors ratio, the $\% \Delta$ depreciation, the $\% \Delta$ capital expenditure, the $\% \Delta$ capital expenditure/total assets, the $\% \Delta$ return on closing equity and the $\% \Delta$ operating profit/total assets variables capture information about future earnings. The results are presented in table 3.8.
Table 3.8 Stepwise Regression Analysis For The Chemical Industry Examining Whether The \% $\Delta$ Accounting Descriptors Jointly Describe Subsequent Earnings Changes For The Period 1980-88.

| Accounting Variables | Coefficient | Standard Error | t-ratio | problti $=$ =x |
| :---: | :---: | :---: | :---: | :---: |
| \% ${ }^{\text {adeblors ratio }}$ | 0.59678 | 0.1427 | 4.183 | 0.00005 |
| \% $\Delta$ depreciation | 0.45117 | 0.9076E-01 | 4.971 | 0.00000 |
| \% $\Delta$ capital expenditure | -0.68730E-01 | $0.2458 \mathrm{E}-01$ | -2.796 | 0.00597 |
| \% $\Delta$ capital expenditure/total assets | 0.74673E-01 | 0.3530E-01 | 2.115 | 0.03635 |
| \%dreturn on closing equity | -0.46554 | 0.1007 | -4.625 | 0.00001 |
| \% $\Delta$ operating profit/sales | 0.65018 | 0.1528 | 4.254 | 0.00004 |

The $\% \Delta$ capital expenditure variable is also reported to capture information about future earnings changes in the multinomial analysis.

## Concluding Remarks

The findings, via logit, suggest that some financial statement report numbers exhibit information concerning the direction of one - year ahead earnings changes. However, the predictive ability of some of these financial statement numbers disappears once outliers are deleted from the sample. Only, four accounting descriptors persist to exhibit predictive ability of future earnings changes in both binary specification methods [first, where outliers are considered and second, where outliers are deleted]. These accounting descriptors are the debtors ratio, the \% debtors ratio, the sales/total assets and the $\% \Delta$ total assets variables.

To further test whether the predictive ability of some accounting descriptors about future earnings changes is due to outliers and further whether the accounting descriptors can predict the size of the $\% \Delta$ operating profit and not just the sign, each accounting descriptor is included as the sole explanatory variable in a univariate regression model. Different descriptors are found to describe earnings changes one year ahead. Only, the sales/total assets and the $\% \Delta$ total assets variables also exhibit information about future earnings changes in both the univariate logit and regression analysis. The two accounting variables mentioned do capture information about future earnings changes and this ability of theirs is not caused by outliers.

Having examined the chemical and stores industries separately, I examine in the following section the stores and chemical industries together. The same tests are also applied here.

## Stores and Chemical Industries Together

## Binary Specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit

## Univariate Logit Analysis

To examine which accounting descriptors exhibit information about future earnings changes for the stores and chemical industries together, each descriptors is included as the sole explanatory variable in the univariate logit model. A direct comparison with the OP results can be made when stores and chemical industries are tested together for the whole period 1980-88. During this period, 19 accounting descriptors [see appendix to this chapter, table A3a] exhibit information concerning the direction of future earnings changes.

Examining the Stores and Chemical Industries together, the 19 descriptors whose coefficient estimates are significant at the 0.10 level are retained. Notice that all the accounting descriptors exhibit same signs with the accounting descriptors coefficient signs OP report. Moreover, attention must be drawn on what Greig (1992) argues that the "Pr" measure might capture industries characteristics.

No attempt is made here to explain the relationship between the accounting descriptors and the $\% \Delta$ in operating profit since analytical explanation has been provided when the two industries are tested separately.

Table 3.9: Stores and Chemical Industries Tested Together Comparison between Ou and Penman's paper with this research's accounting variables coefficients signs examining their relationship with the \% $\Delta$ operating profit.

| Accounting Descriptors | Ou and Penman coefficients |  | This research's coefficients |

| working capita/total assets | -0.2258 | -0.0538 | -0.0146 |
| $\Delta$ working capital |  |  | -21.049 |

## Multinomial Logit Analysis

In the second stage, in order to test whether the accounting descriptors [whose coefficient are significant at 0.10 level in the univariate analysis] jointly describe the subsequent earnings changes, we run a multinomial logit model. Throughout the period 1980-88, the net profit margin, the $\% \Delta$ working capital and the depreciation variables contain information about future earnings changes. The results are shown in table 3.10.

Ou and Penman report that the $\% \Delta$ dividend per share, the $\% \Delta$ capital expenditure/total assets with one year lag, the return on total assets, the operating income over total assets, the repayment of long term debt as \% of total LT debt and the intercept jointly describe the direction of future earnings changes.

Table 3.10: Multinomial Logit Estimation For The Stores and Chemical Industries Examining Whether The Accounting Descriptors Selected Jointly Describe Future Earnings Changes For The Period 1980-88.

| Accounting Descriptors | Accounting Coefficient | Standard Error | t-statistic | probltl> $=\boldsymbol{x}$ |
| :--- | :--- | :--- | :--- | :--- |

| \% $\Delta$ return on closing equity | -0.12780 | 0.9543 | -2.347 | 0.06186 |
| net profit margin | -1.7893 | 0.4560 | -1.456 | 0.14074 |
| $\Delta$ sales/cash | 0.33210 | 0.46333 | 1.465 | 0.51200 |
| \% sales/cash | -0.62260 | 0.5223 | -1.331 | 0.11013 |
| $\Delta$ sales/inventory | -0.65206 | 0.4788 | -0.478 | 0.87237 |
| $\Delta$ total assets | -0.12780 | 0.9543 | -2.347 | 0.06186 |
| working capital/total assets | -1.78931 | 0.4560 | -1.456 | 0.14074 |
| $\Delta$ working capital | $0.45701 \mathrm{E}-01$ | $0.3163 \mathrm{E}-01$ | 1.456 | 0.66001 |

## Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit with outliers being deleted

## Univariate Logit Analysis

To examine whether the accounting descriptors' ability to contain information about future earnings is caused by outliers, we delete outliers from the dataset and each descriptor is included as the sole explanatory variable in the univariate logit estimation [see appendix to this chapter, table A3b]. The findings suggest that the debtors ratio, the sales, the $\% \Delta$ in net profit margin and the cash flow/total debt are the descriptors still exhibiting information about future earnings changes. Notice that different accounting descriptors, altogether, have been found to exhibit information about future earnings changes in the univariate logit estimation where outliers are not deleted. Evidence suggests that the accounting descriptors' ability to contain information about subsequent earnings changes is caused by the outliers.

## Multinomial Logit Analysis

To examine whether the accounting descriptors' ability whose coefficient is significant at the 0.10 level in the univariate analysis, jointly describe subsequent earnings changes and whether this predictive ability is due to outliers or not, we run a multinomial logit model. The results are shown in table 3.11.

Table 3.11: Multinomial Logit Estimation For The Stores and Chemical Industries Examining Whether The Accounting Descriptors Selected Jointly Describe Future Earnings Changes During The Period 1980-88.

| Accounting Descriptors | Coefficient | Standard Error | t-statistic | prob\|tl> $=\boldsymbol{x}$ |
| :--- | :--- | :--- | :--- | :--- |
| debtors ratio | $0.16898 \mathrm{E}-02$ | $0.1235 \mathrm{E}-02$ | 1.368 | 0.17123 |
| cash flow.Jtotal debt | $0.95668 \mathrm{E}-01$ | $0.5385 \mathrm{E}-01$ | 1.777 | 0.07564 |
| $\Delta$ uses | $-0.86884 \mathrm{E}-01$ | $0.6520 \mathrm{E}-01$ | -1.333 | 0.18268 |

The only variable exhibiting information about future earnings changes is the $\Delta$ uses.

## Regression Analysis

## Univariate Regression Analysis

To further examine whether accounting descriptors' ability to contain information about future earnings is indeed caused by outliers and whether the accounting descriptors can predict the size of the $\% \Delta$ operating profit or just the sign, a univariate regression estimation is run. In the univariate regression analysis [see A3c] the accounting descriptors which contain information about future earnings are the \% $\Delta$ inventory/total assets, the $\% \Delta$ sales, the $\Delta$ depreciation/fixed assets, the return on opening equity, the $\% \Delta$ return on opening equity, the times interest earned and the return on closing equity. None of the above accounting descriptors are reported to capture information about future earnings when the stores and chemical industries are examined separately. None appears to contain information about future earnings changes under the two univariate logit models [first model with outliers and second model without outliers] explained in previous sections. Moreover none is the same as the ones presented by OP [Ou and Penman (1989), p. 307].

## Stepwise Regression

In the stepwise regression, during the period 1980-88, the $\% \Delta$ quick assets ratio, the $\% \Delta$ depreciation/fixed assets and the $\% \Delta$ capital expenditure variables jointly exhibit information concerning the direction of future earnings changes. The results are presented in table 3.12.

Table 3.12 Stepwise Regression Analysis For The Stores and Chemical Industry Examining Whether The \% $\Delta$ Accounting Descriptors Jointly Describe Subsequent Earnings Changes For The Period 1980-88.

| Accounting Variables | Coefficient | Standard Error | t-ratio | problt $\mid>=x$ |
| :--- | :--- | :--- | :--- | :--- |
| \% $\Delta q u i c k ~ a s s e t s ~ r a t i o ~$ | 0.22676 | 0.1227 | 3.283 | 0.00045 |
| \% $\Delta$ depreciation/fixed assets | 0.07217 | $0.9446 \mathrm{E}-01$ | 4.771 | 0.00010 |
| \% $\Delta$ capital expenditure | $-0.65550 \mathrm{E}-01$ | $0.2008 \mathrm{E}-01$ | -2.456 | 0.00697 |

### 3.5 CONCLUDING REMARKS

This chapter takes an earnings change prediction approach to investigate whether U.K stores and chemical industries annual financial statement report numbers contain information concerning the direction (via logit) and size (via regression) of one-year ahead earnings changes. It provides empirical evidence for a predictive information link between these financial statement numbers and future earnings changes.

## Stores Industry

The findings (via logit) suggest that some financial accounting variables exhibit information concerning the direction of next year's earnings changes. However, the ability of some of these accounting variables to describe future earnings changes disappears once outliers [these may be extraordinary items] are deleted from the sample. For example, the inclusion in net income of a large write-down for a plant closing can cause an outlier.

The accounting descriptors which are robust to all the logit tests carried out
[with and without outliers] are the following:

- \% $\Delta$ current ratio;
- inventory;
- times interest earned; and
- return on total assets.

In the multinomial analysis, the only accounting variable which captures information about future earnings changes is the

- \% $\Delta$ current ratio.

The $\% \Delta$ current ratio appears in both multivariate logit models run [ with outliers and without outliers].

The findings (via regression) suggest that the accounting descriptors can predict the size of the $\% \Delta$ operating profit as well as the sign. However, different accounting variables from the ones reported in the logit models are found to capture information concerning the size and sign of the $\% \Delta$ operating profit oneyear ahead in the regression model. This might be attributed to the different methodologies used.

It is noteworthy that the accounting variable

- $\Delta$ inventory/turnover,
found to exhibit information about future earnings changes sign and size, is also reported by OP (1989a) as one of six descriptors to describe the sign of the future earnings changes for the periods 1965-72 and 1973-77.

## Chemical Industry

The findings (via logit) suggest that some financial accounting variables exhibit information concerning the direction of next year's earnings change. However, the ability of some of these accounting variables to describe future earnings changes disappears once outliers [these may be extraordinary items] are deleted from the sample.

The accounting variables which are robust to all the logit tests carried out [with and without outliers] and predict next year's earnings changes are

- the sales/total assets;
- the \% $\Delta$ total assets;
- the debtors ratio; and
- the sales/total assets.

In the multinomial analysis, the accounting variables which jointly describe future earnings changes are the

- debtors ratio; and
- the sales/ total assets.

These two accounting variables appear in both multinomial logit models employed [with and without outliers].

The findings (via regression) suggest that the accounting descriptors can predict the size of the $\% \Delta$ operating profit as well as the sign. The two accounting variables which exhibit information about the size and sign of the $\% \Delta$ operating profit one-year ahead are the following:

- sales/total assets; and
- \% $\Delta$ total assets.

Ohlson (1991) recommends the aggregated total assets as the accounting descriptor which can shed light on the valuation concept ${ }^{10}$.

## Stores and Chemical Industries Together

The findings (via logit) suggest that, when industries are aggregated, some financial accounting variables exhibit information concerning the direction of next year's earnings change. However, the ability of all these accounting variables to describe future earnings changes one-year ahead disappears once outliers [these may be extraordinary items] are deleted from the sample.

The findings (via regression) suggest that the accounting descriptors can predict the size of the $\% \Delta$ operating profit as well as the sign. The accounting variables which exhibit information about the size and sign of the $\% \Delta$ operating

[^20]profit one-year ahead are the following:

- $\Delta$ inventory/total assets;
- \% $\Delta$ sales;
- $\Delta$ depreciation/fixed assets;
- the return on opening equity;
- the $\% \Delta$ return on opening equity;
- the times interest earned and
- the return on closing equity.

None of the above accounting descriptors are reported to capture information about the sign and size of the future earnings when the stores and chemical industries are examined separately. None appears to contain information about future earnings changes under the two univariate logit models [first model with outliers and second model without outliers]. Moreover none is the same as the ones presented by OP [Ou and Penman (1989), p. 307].

## Concluding Remarks

Overall the findings suggest that the power of the tests to predict the sign (via logit) and size (via regression) when the industries are aggregated is poor. When industries are tested separately, the findings reveal that different accounting descriptors describe future earnings sign and size changes in different industries. However, it must be noticed that the times interest earned variable exhibits information about the direction (via logit) of future earnings changes in the stores industry while when the two industries stores and chemical are aggregated, the times interest earned variable predicts the size (via regression) of the future earnings changes.

Overall the findings are in accordance with Greig's (1992) argument that "the summary measure "Pr" of the OP analysis is a function of accounting ratios. Ratios vary systematically across firms as a function of future earnings changes and also vary systematically cross-sectionally as a function of risk, size and determinants of expected returns [ Greig (1992), p. 415]. In other words, economic
factors cause the link between financial statement numbers and future earnings changes.

But the question asked now is whether the overall results are a consequence of a systematic relationship between these industry accounting descriptors and future earnings changes and whether expert analysts and investors can detect this relationship. The answer might lie on whether these accounting descriptors capture the "temporary" or " permanent" changes in current earnings. The permanent component will persist over time while the transitory will be only time-specific.

Thus the consistency of the accounting descriptors' coefficient signs and size across time and across industry needs to be tested. These issues are dealt with in chapter 4.

## CHAPTER FOUR

Do Accounting Descriptors Capture the Temporary or Permanent changes in current earnings?

Evidence For The U.K.

### 4.1 INTRODUCTION

In chapter 3, evidence suggests that some financial statement report numbers describe next year's earnings changes. But are the overall results a consequence of a systematic relationship between these financial statement numbers and future earnings? And how can expert analysts and investors detect this relationship if it is not stable over time? These are some of the questions raised by the findings in chapter 3.

The purpose of this chapter is to examine the consistency of the coefficient signs of the accounting descriptors containing information about future earnings, across time and across industries. Specifically, an investigation is carried out, to examine whether accounting descriptors exhibiting such informational characteristic about future earnings, capture the temporary or permanent change in current earnings.

The chapter is organised as follows: section 4.2 describes the hypotheses tested; section 4.3 explains the experimental design; section 4.4 presents the accounting descriptors coefficients signs which contain information about future earnings via univariate and multinomial logit estimations; section 4.4 also presents the accounting descriptors coefficients signs which contain information about future earnings via univariate regression estimation. section 4.5 contains the conclusion.

### 4.2 HYPOTHESES TESTED

To examine whether the accounting descriptors containing information about future earnings capture the temporary or permanent changes in current earnings, two hypotheses are tested:

- $\quad \mathrm{H}_{1}$ : The accounting descriptors containing information about future earnings capture the temporary changes in current earnings i.e do not exhibit the same informational characteristic over all sub-periods and the period 1980-88.
- $\quad \mathrm{H}_{2}: \quad$ The accounting descriptors containing information about future earnings capture the permanent changes in current earnings i.e exhibit the same informational characteristic over all sub-periods and the period 198088.

### 4.3 EXPERIMENTAL DESIGN

The logit earnings change prediction models are estimated, first, based on a pooled data set of 69 companies, from stores and chemical industries, over the sub-periods 1980-84, 1981-85, 1982-86, 1983-87 and 1984-88; second, on a data set of 40 companies of the stores industry over the sub-periods 1980-84, 1981-85, 1982-86, 1983-87 and 1984-88; third, on a data set of 29 chemical companies of the chemical industry again over the sub-periods 1980-84, 1981-85, 1982-86, 1983-87 and 1984-88.

In the first stage, each descriptor is included as the sole explanatory variable in a LOGIT change earnings prediction model. In a second stage, in order to examine whether the accounting descriptors jointly describe subsequent earnings changes, all descriptors whose coefficient estimates are found significant at the 0.10 level in the univariate logit estimation, are included in a multinomial logit model.

Univariate regression estimations are run as well since it is believed that the binary specification of the logit analysis throws away information. The estimates within each estimation period are not from independent observations, however.

In each logit model, the dependent variable is specified in two ways: first, the distribution of the $\% \Delta$ operating profit is partitioned by the mean; second, the distribution of the $\% \Delta$ operating profit is partitioned by the mean, but outliers are deleted in order to examine whether the ability of the accounting descriptors to contain information about future earnings is driven by outliers [these might be extraordinary items].

The following equation is employed for testing the two hypotheses over the sub-periods 1980-84, 1981-85, 1982-86, 1983-87 and 1980-84:

$$
\begin{equation*}
\% \Delta \text { Operatingprofit } i_{i t}=a_{0}+a_{1} X_{i t}+u_{i t} \tag{4.1}
\end{equation*}
$$

Under efficient market hypothesis, the null hypothesis accepts that al=0, that is, that accounting descriptors do not contain information about future earnings. The alternative hypothesis accepts that al$\neq 0$, that is, that accounting descriptors exhibit information about future earnings changes.

### 4.4 IDENTIFICATION OF ACCOUNTING DESCRIPTORS WHICH CONTAIN INFORMATION ABOUT FUTURE EARNINGS

## Stores Industry

## Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit

## Univariate logit analysis

To Identify which accounting descriptors exhibit information about future earnings changes, each descriptor is included as the sole explanatory variable in the univariate logit analysis. The coefficient estimates for all 83 accounting descriptors are reported in the appendix to this chapter, table A1, along with a $t$-statistic (and p-value). In the sub-period 1980-84, nineteen (19) of the coefficient estimates have p-values less than 0.10. Similar consistency is observed (in the first period) for descriptors with p-values less than 0.10 in the subsequent periods. In the sub-period 1981-85, sixteen (16) of the coefficient estimates have p-values less than 0.10 [see appendix to this chapter, table Ala], during the sub-period 1982-86, fourteen (14) of the coefficient estimates [see table Alb], during the sub-period 1983-87, fourteen (14) have p-values less than 0.10 [see appendix to this chapter, table A1c] while in the sub-period, 1984-88, again fourteen (14) descriptors have p-value less than 0.10 [see appendix to this chapter, table Ald]. The consistency of the sign and the significance levels of the estimated coefficients on the descriptors over the six estimation periods requires emphasis though. The results are shown in table 4.1.

Table 4.1 Univariate Logit Estimation For The Stores Industry Examining Whether The Accounting Descriptors Exhibit Information About Future Earnings* Changes For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

a The maximum likeliiood estimate of the coefficient on the accounting descriptor.
b The p -values of the t -statistic are all significant at the 0.10 level.

* The tests for the period 1980-88 are carried out in chapter 3. However, the accounting coefficients, the standard error, the $t$ statistic and p-values for the period 1980-88 are displayed in the appendix to this chapter, table Ale.

Of the accounting descriptors displayed in the table 4.1 , only the $\% \Delta$ in current ratio and the times interest earned variables contain information about future earnings over all periods examined. The current ratio, the $\Delta$ current ratio, the depreciation/fixed assets, the $\% \Delta$ return on opening equity and the net profit margin variables exhibit information about future earnings over the periods $1980-87$ and 1980-88. In either case, this indicates that we have captured attributes of firms that demonstrate some regularity in generating earnings. However, evidence suggest that the ability of the accounting descriptors to contain information about future earnings changes are timespecific. Only in the case of the $\% \Delta$ in current ratio and the times interest earned variables, the findings suggest that these two accounting descriptors capture the permanent changes in current earnings.

## Multinomial Analysis

To examine the significant ability of the accounting descriptors to jointly describe subsequent earnings changes, we carry out a multinomial logit analysis by including only the accounting descriptors whose coefficient estimates are significant at the 0.10 level in the univariate analysis.

Table 4.2: Multinomial Logit Estimation For The Stores Industry Examining Whether The Accounting Descriptors Jointly Exhibit Information About Future Earnings* Changes For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

| Accounting Descriptors | 1980-84 | 1981-85 | 1982-86 | 1983-87 | 1984-88 | 1980-88 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| current ratio | $\begin{aligned} & -3.1802^{n} \\ & (-1.736)^{6} \end{aligned}$ |  |  |  |  |  |
| $\% \Delta$ current ratio |  |  | $\begin{aligned} & -0.04999 \\ & (-4.244) \end{aligned}$ |  |  |  |
| operating profitsales | $\begin{aligned} & -123.96 \\ & (-1.929) \end{aligned}$ |  |  |  |  |  |
| depreciation/fixed assets |  | $\begin{aligned} & 0.28282 \\ & (6.534) \end{aligned}$ |  |  |  |  |
| return on closing equity |  | $\begin{aligned} & -0.00604 \\ & (-2.297) \end{aligned}$ |  |  |  |  |
| \% $\Delta$ sales/cash |  | $\begin{aligned} & 0.01050 \\ & (3.725) \end{aligned}$ |  |  |  |  |
| \% $\Delta$ inventory |  |  | $\begin{aligned} & -0.14776 \\ & (-1.674) \end{aligned}$ |  |  |  |

There does not appear to be much consistency in the accounting descriptors included in the models for all the six periods. Accounting descriptors capture only the "temporary" changes in current earnings. However, these are multinomial models and the inclusion of a particular variable and the sign of the estimated coefficient will depend on variables already in the model at the relevant step in the step-wise procedure.

## Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit with outliers being deleted.

## Univariate Logit Analysis

In this alternative method, we test whether the ability of the accounting descriptors to exhibit information about future earnings changes is driven by the outliers. Thus outliers are deleted from the $\% \Delta$ operating profit variable. The coefficient estimates for all 83 accounting descriptors are given in the appendix to this chapter, table A4, along with a $t$-statistic (and p-value). In the sub-period 1980-84, six (6) of the coefficient estimates have p-values less than 0.10 . Similar consistency is observed (in the first period) for descriptors with p-values less than 0.10 in the subsequent periods. In the sub-period 1981-85, seventeen (17) of the coefficient estimates have p-values less than 0.10 [see appendix to this chapter, table A4a]. During the sub-period 198286 , fourteen (19) of the coefficient estimates have p-values less than 0.10 [see appendix to this chapter, table A4b]. In the sub-period 1983-87, fourteen (14) have p-values less than 0.10 [see appendix to this chapter, table A4c] while during the subperiod, 1980-84, fourteen (14) variables have p-value less than 0.10 [see appendix to this chapter, table A4d]. The consistency of the sign and the significance levels of the estimated coefficients on the descriptors over the six estimation periods requires emphasis. The results are shown in table 4.3.

Table 4.3 Univariate Logit Estimation For The Stores Industry Examining Whether The Accounting Descriptors Exhibit Information About Future Earnings* Changes For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88

| a The maximum Inkenhood estimate of the coetificient on the accounting descriptor. |  |  |  |  |  |
|  |  |  |  |  |  |
| *The tests for the period 1980-88 are carried out in chapter 3 . However, the accounting coefficients, the standard error, the $t-$ statistic and p-values for the period 1980-88 are displayed in the appendix to this chapter, table A4e. |  |  |  |  |  |

The majority of the accounting descriptors displayed in the table 4.3, have the same sign on the estimated coefficient in all periods examined. This indicates that we have captured attributes of firms that demonstrate some regularity in generating earnings. However, it must be emphasized that none of the accounting descriptors contains information about future earnings over all periods examined. This indicates that the accounting descriptors capture only the temporary changes in current earnings. The current ratio and the times interest earned descriptors no longer exhibit information about the future earnings changes over all periods. The findings suggest that these two accounting descriptors' ability to contain information about future earnings is driven indeed by outliers.

## Multinomial Logit Analysis

The multinomial models of all the six periods examined are summarised in table 4.4. The various test statistics indicate significant ability of the descriptors to jointly describe subsequent earnings changes even when outliers are deleted, over some periods. However, there does not appear to be much consistency in the descriptors included in the models for all the six periods.

Table 4.4: Multivariate Logit Estimation For The Stores Industry Examining Whether The Accounting Descriptors Jointly Exhibit Information About Future Earnings* Changes For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

| Accounting Descriptors | $1980-84$ | $1981-85$ | $1982-86$ | $1983-87$ | $1984-88$ | $1980-88$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| sales/cash | $-0.00098^{\circ}$ |  |  |  |  |  |
| sales | $(-1.709)^{\mathrm{b}}$ |  | -0.0000 |  |  |  |
|  |  | $(-1.772)$ |  |  |  |  |
| $\Delta$ net profit margin |  | 0.77959 |  |  |  |  |
| $\Delta$ working capital/total assets |  | $(1.871)$ |  |  |  |  |
|  |  |  | -8.2726 |  |  |  |
|  |  |  | $(-2.236)$ |  |  |  |
|  |  |  |  |  |  |  |

a The maximum likelihood estimate of the coefficient of the accounting descriptor.
b The p-values of the $t$-statistic are all significant at the 0.10 level.

* The accounting coefficient, $t$-statistic and p-values are reported in the tables A4i, A4ai, A4bi, A4ci, A4di, A4ei.

Results indicate that the accounting descriptors found to contain information about future earnings in the univariate models, do no jointly describe subsequent earnings changes. Again, it must be mentioned that these are multinomial models and the inclusion of a particular variable and the sign on its estimated coefficient will depend on variables already in the model at the relevant step in the step-wise procedure.

## Regression Analysis

## Univariate Regression Analysis

To further examine whether the accounting descriptors' ability to contain information about future earnings changes is caused by outliers and whether the accounting descriptors predict the size of the $\% \Delta$ operating profit and not just the sign, each accounting descriptor is included as the sole explanatory variable in a univariate regression model.

Table 4.5: Univariate Regression Estimation For The Stores Industry Examining Whether The Accounting Descriptors Exhibit Information About Future Earnings* Changes For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88

| $\Delta$ working capital/total assets |  |  |  |  |  | $\begin{aligned} & -1.2115 \\ & (-1.8320) \end{aligned}$ |

None of the accounting descriptors exhibits information about future earnings changes over all periods. The findings suggests that outliers drive the accounting descriptors' ability to contain information about future earnings changes. It is noteworthy that different accounting descriptors are captured to have information about future earnings changes under the univariate logit and regression analyses.

In the next section, I apply the same tests over the same six periods examined for the stores industry, to examine the consistency of the coefficients signs of the accounting descriptors containing information about future earnings changes in the chemical industry.

## Chemical Industry

## Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit

## Univariate Logit Analysis

We examine which accounting descriptors exhibit information about future earnings changes by including each accounting descriptor as the sole explanatory variable in the univariate logit model. The coefficient estimates for all 83 accounting descriptors are given in tables in the appendices along with a t-statistic (and p-value). In the subperiod 1980-84, eleven (11) of the coefficient estimates have p -values less than 0.10 [see appendix to this chapter, table A2]. Similar consistency is observed (in the first sub-period) for descriptors with p -values less than 0.10 in the subsequent periods. In the sub-period 1981-85, thirteen (13) of the coefficient estimates have p -values less than 0.10 [see appendix to this chapter, table A2a], in the sub-period 1982-86, thirteen (13) of the coefficient estimates have p -values less than 0.10 [see appendix to this chapter, table A2b]. In the sub-period 1983-87, eleven (11) have p-values less than 0.10 [see appendix to this chapter, table A2c] while in the sub-period, 1984-88, sixteen (16) variables have p -value less than 0.10 [see appendix to this chapter, table A2d]. The consistency of the sign and the significance levels of the estimated coefficients on the descriptors over the six estimation periods requires emphasis, once more. The results are shown in table 4.6 .

Table 4.6 Univariate Logit Estimation For The Chemical Industry Examining Whether The Accounting Descriptors Exhibit Information About Future Earnings Changes* For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

The results in table 4.6 indicates that we have captured attributes of firms that demonstrate some regularity in generating earnings. Moreover, the debtors ratio, the return on opening equity and the return on total assets exhibit the same informational characteristic for future earnings over all periods examined. This indicates that the three accounting descriptors mentioned, capture the permanent change in current earnings.

## Multinomial Logit Analysis

The multinomial models of all the six periods examined are summarised in table 4.7. The various test statistics indicate significant ability of the descriptors to jointly describe subsequent earnings changes in some periods. However, there does not appear to be much consistency in the descriptors included in the models for the six periods.

Table 4.7: Multinomial Logit Estimation For The Chemical Industry Examining Whether The Accounting Descriptors Jointly Exhibit Information About Future Earnings Changes* For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

However, these are multinomial models and the inclusion of a particular variable and the sign on its estimated coefficient will depend on variables already in the univariate model.

## Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit with outliers being deleted.

## Univariate Logit Analysis

To examine whether the accounting descriptors' ability to exhibit information about future earnings changes is driven by outliers, outliers are deleted from the sample data and each accounting descriptor is included as the sole explanatory variable in a univariate logit model.

The debtors ratio, the return on opening equity and the return on total assets capture permanent changes in current earnings. The results are shown in table 4.8.

The coefficient estimates for all 83 accounting descriptors are given in tables in the appendices along with a t-statistic (and p-value). In the sub-period 1980-84, seven (7) of the coefficient estimates have p -values less than 0.10 [see appendix to this chapter, table A4]. Similar consistency is observed (in the first sub-period) for descriptors with p-values less than 0.10 in the subsequent periods. In the sub-period 1981-85, six (6) of the coefficient estimates have p-values less than 0.10 [see appendix to this chapter, table A4a]. During the sub-period 1982-86, eleven (11) of the coefficient estimates have p-values less than 0.10 [see appendix to this chapter, table A4b]. In the sub-period 1983-87, fifteen (15) have p-values less than 0.10. During the sub-period [see appendix to this chapter, table A4c], 1984-88, ten (10) variables have p-value less than 0.10 [see table A4d]. The consistency of the sign and the significance levels of the estimated coefficients on the descriptors over the six estimation periods requires emphasis again.

Table 4.8 Univariate Logit Estimation For The Chemical Industry Examining Whether The Accounting Descriptors Exhibit Information About Future Earnings* Changes For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

a The maximum likelihood estimate of the coefficient on the accounting descriptor.
b The $p$-values of the $t$-statistic are all significant at the 0.10 level.

* The tests for the period 1980-88 are carried out in chapter 3. However, the accounting coefficients, the standard error, the $t$ statistic and p -values for the period 1980-88 are shown in the appendix to this chapter, table A2e.

Results indicate that we have captured attributes of firms demonstrating some regularity in generating earnings. However, none of the accounting descriptors exhibit the same informational characteristic about future earnings over all the periods
examined. This indicates that the accounting descriptors only capture the temporary changes in the current earnings and that the outliers have driven the empirical results reported in the univariate logit analysis where outliers are not deleted.

## Multinomial Logit Analysis

The multinomial models of all the six periods examined are summarised in table 4.9. The various test statistics indicate significant ability of the descriptors to jointly describe subsequent earnings changes, even when outliers are deleted. There does not appear to be much consistency in the descriptors included in the models for the six periods. Once again, evidence suggests that the accounting descriptors capture the "temporary" and not "permanent" changes in current earnings.

Table 4.9: Multinomial Logit Estimation For The Chemical Industry Examining Which Accounting Descriptors Jointly Exhibit Information About Future Earnings Changes For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

a The maximum likelihood estimate of the coefficient on the accounting descriptor.
b The p-values of the $t$-statistic are all significant at the 0.10 level.

* The accounting coefficient, t-statistic and p-values are displayed in tables A4i, A4ai, A4bi, A4ci, A4di, A4ei .

The $\% \Delta$ operating profit/sales variable predicts future earnings changes over the period 1983-88 while the return on closing equity variable predicts future earnings changes over the period 1983-88 and 1980-88.

## Regression Analysis

## Univariate Regression Analysis

To further examine whether the accounting descriptors' ability to exhibit information about future earnings changes is caused by the outliers and whether the accounting descriptors can predict the size of the $\% \Delta$ operating profit variable or just the sign, each accounting descriptor is included as the sole explanatory variable in a univariate regression model. The results are shown in table 4.10.

Table 4.10: Univariate Regression Estimation For The Chemical Industry Examining Whether The Accounting Descriptors Exhibit Information About Future Earnings Changes For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

a The maximum Iikelihood estimate of the coefficient on the accounting descriptor.
$b$ The $p$-values of the $t$-statistic are all significant at the 0.10 level.

* The accounting coefficient, t-statistic and p-values are displayed in tables A8, A8a, A8b, A8c, A8d, A8e.

Results indicate that the accounting descriptors demonstrate some regularity in generating earnings. Moreover, the $\Delta$ current ratio, the $\% \Delta$ current ratio and the $\Delta$ working capital exhibit some regularity in containing information about future earnings over the period 1980-87. The return on opening equity, the $\Delta$ inventory/total assets, the $\% \Delta$ sales/total assets exhibit some regularity in containing information about future earnings over the period 1982-87 while the $\% \Delta$ working capital exhibits this characteristic over the period 1980-86. However, the findings suggest that the ability of the accounting descriptors to exhibit information about future earnings changes is time-specific.

# Stores and Chemical Industries Together 

## Binary specification $(0,1)$ is formed based on the mean of the \% $\Delta$ operating profit

## Univariate Logit Analysis

To identify which accounting descriptors predict the direction of one-year ahead future earnings, each accounting descriptor is included as the sole explanatory variable in a univariate logit model. The coefficient estimates for all 83 accounting descriptors are shown in the appendix to this chapter, table A3, along with a $t$-statistic (and $p$-value). In the sub-period 1980-84, of the coefficient estimates have p-values less than 0.10 . Similar consistency is observed (in the first sub-period) for descriptors with p-values less than 0.10 in the subsequent periods. In the sub-period 1981-85, eleven (11) of the coefficient estimates have p-values less than 0.10 [see appendix to this chapter, table A3a]. During the sub-period 1982-86, eleven (11) of the coefficient estimates have pvalues less than 0.10 [see appendix to this chapter, table A3b]. In the sub-period 1983-87, twenty four (24) have p-values less than 0.10 [see appendix to this chapter, table A3c] while in the sub-period, 1984-88, seventeen (17) variables have p-value less than 0.10 [see appendix to this chapter, table 3Ad]. The consistency of the sign and the significance levels of the estimated coefficients on the descriptors over the six estimation periods are displayed in table 4.11.

Table 4.11 Univariate Logit Estimation For The Stores and Chemical Industries Examining Whether The Accounting Descriptors Exhibit Information About Future Earnings* Changes The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 198088.

a The maximum inkelinood estimate of the coefficient on the accounting descriptor
$b$ The $p$-values of the $t$-statistic are all significant at the 0.10 level.

* The tests for the period 1980-88 are carried out in chapter 3. However, the accounting coefficients, standard error, t-statistic and p-values are shown in the appendix to this chapter, table A3e.

The $\Delta$ current ratio variable predicts the future earnings changes one-year ahead during the period 1983-88. The net profit margin variable predicts future earnings changes one-year ahead during the period 1982-88. The accounting descriptors demonstrate some regularity in generating future earnings but none of the accounting descriptors exhibit the same characteristic over all the periods examined. This indicates that the accounting descriptors only capture the temporary changes in current earnings.

## Multinomial Logit Analysis

The multinomial models of all the six periods examined are summarised in table 4.12. The various test statistics indicate significant ability of the descriptors to jointly describe subsequent earnings changes. However, there does not appear to be much consistency in the descriptors included in the models for the six periods.

Table 4.12: Multinomial Logit Estimation For The Stores and Chemical Industries Examining Whether The Accounting Descriptors Jointly Exhibit Information About Future Earnings* Changes During The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

a The maximum likeihood estimate of the coefficient on the accounting descriptor.
b The p -values of the t -statistic are all significant at the 0.10 level.

* The accounting coefficient, $t$-statistic and p-values are displayed in tables A3i, A3ai, A3bi, A3ci, A3di, A3ei.

Evidence suggests that the accounting descriptors displayed in table 4.12 jointly capture temporary and not permanent changes in current earnings.

## Binary specification $(0,1)$ is formed based on the mean of the $\% \Delta$ operating profit with outliers being deleted.

## Univariate Logit Analysis

To examine whether the accounting descriptors' ability to predict the direction of oneyear ahead future earnings changes is caused by outliers, each accounting descriptor is included as the sole explanatory variable in a univariate logit model, but outliers are deleted. The coefficient estimates for all 83 accounting descriptors are given in the appendix to this chapter, table A6, along with a $t$-statistic (and p-value). In the subperiod 1980-84, four (4) of the coefficient estimates have p -values less than 0.10 . Similar consistency is observed (in the first sub-period) for descriptors with p-values less than 0.10 in the subsequent periods. In the sub-period 1981-85, three (3) of the coefficient estimates have p-values less than 0.10 [see appendix to this chapter, table A6a]. During the sub-period 1982-86, thirteen (13) of the coefficient estimates have p-values less than 0.10 [see appendix to this chapter, table A6b]. In the sub-period 1983-87, five (5) have p-values less than 0.10 [see appendix to this chapter, table A6c]. During the sub-period, 1984-88, twelve (12) variables have p-value less than 0.10 [see appendix to this chapter, table A6d]. The consistency of the sign and the significance levels of the estimated coefficients on the descriptors over the six estimation periods requires emphasis. The results are shown in table 4.13.

Table 4.13 Univariate Logit Estimation For The Stores and Chemical Industries Examining Whether The Accounting Descriptors Exhibit Information About Future Earnings* Changes For The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

| cash flow/total debt |  |  |  |  |  | $\begin{aligned} & 0.07822 \\ & (2.056) \end{aligned}$ |

The depreciation and $\Delta$ depreciation variables predict the direction of one-year ahead future earnings during the period 1982-88. The accounting descriptors demonstrate some regularity in generating earnings. However, none exhibits this informational characteristic over all the periods examined. Results suggest that accounting descriptors capture only the temporary changes in current earnings. Specifically, the
results suggest that the accounting descriptors found to generate earnings in the binary specification models where outliers are not deleted, are driven by outliers.

## Multinomial Logit Analysis

The final models of all the six periods examined are summarised in table 4.14. The various test statistics indicate significant ability of the descriptors to jointly describe subsequent earnings changes. There does not appear to be much consistency in the descriptors included in the models for the six periods. The findings, once more, indicate that the accounting descriptors capture "temporary"changes in current earnings.

Table 4.14: Multinomial Logit Estimation For The Stores and Chemical Industries Examining Whether The Accounting Descriptors Selected Exhibit Information About Future Earnings* Changes During The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88

## Regression Analysis

## Univariate Regression Analysis

To examine whether the ability of the accounting descriptors to exhibit information about future earnings is caused by outliers and whether the accounting descriptors predict the size of the $\% \Delta$ operating profit variable or just the sign, a univariate regression estimation is carried out. The results are shown in table 4.15.

Table 4.15 Univariate Regression Estimation For The Stores and Chemical Industries Examining Whether The Accounting Descriptors Selected ExhiBIT Information About Future Earnings* Changes During The Periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

Accounting descriptors demonstrate some regularity in generating earnings. The $\% \Delta$ return on opening equity predicts earnings changes over the period 1981-87, while the $\% \Delta$ inventory/total assets, the cash flow/total debt and the total income/cash flow variables predicts earnings changes over the period 1982-88.

### 4.5 CONCLUDING REMARKS

This chapter takes an earnings change prediction approach to investigate the incremental information content of financial statement report numbers over current earnings, during the periods $1980-84,1981-85,1982-86,1983-87$ and 1984-88. It provides empirical evidence for an unsystematic relationship between these financial statement report numbers and future earnings changes over the periods examined.

## Stores Industry

The findings (via logit) suggest that a firm's financial statement report numbers predict the direction of one-year ahead earnings changes over the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88. The accounting descriptors which predict future earnings changes over all the periods examined are

- the $\% \Delta$ current ratio and
- the times interest earned variable.

However, the predictive information link between these two financial descriptors and future earnings changes disappears when the outliers are deleted from the sample.

The findings (via regression) suggest that a firm's financial statement report numbers predict the size as well as the sign of the $\% \Delta$ operating profit variable. However, this predictive ability of the accounting descriptors is not systematic. It is time-specific.

## Chemical Industry

The findings (via logit) suggest that a firm's financial statement report numbers predict the direction of one-year ahead earnings changes over the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88. The accounting descriptors which predict future earnings changes over all the periods examined are

- debtors ratio;
- the return on opening equity and
- the return on total assets.

However, the predictive information link between these two financial descriptors and future earnings changes disappears when the outliers are deleted from the sample.

The findings (via regression) suggest that a firm's financial statement report numbers predict the size as well as the sign of the $\% \Delta$ operating profit variable. However, this predictive ability of the accounting descriptors is not systematic. It is time-specific.

## Stores and Chemical Industries Together

The findings (via logit) suggest that a firm's financial statement report numbers do not predict the direction of one-year ahead earnings changes over the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

The findings (via regression) suggest that a firm's financial statement report numbers predict the size as well as the sign of the $\% \Delta$ operating profit variable. However, this predictive ability of the accounting descriptors is not systematic. It is time-specific.

## Concluding Remarks

Overall the findings (via logit) suggest that a firm's financial statement report numbers predict the direction of one-year ahead earnings changes over the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88. However, there is not a systematic relationship link between the financial statement report numbers and future earnings changes. The predictive ability of the financial statement report numbers regarding future earnings changes is time-specific. The findings are in accordance with Woodmore (1991) ${ }^{1}$ and Holthausen and Larcker (1992) ${ }^{2}$.

[^21]The accounting descriptors, under the LOGIT methodology, are found to predict the sign of the $\% \Delta$ operating profit more systematically than under the REGRESSION methodology. In addition, under the regression analysis, the accounting descriptors do not seem so systematic in predicting the size of the $\% \Delta$ operating profit.

The accounting variables exhibiting incremental information content over current earnings in stores industry differ from those exhibiting incremental information content over current earnings in chemical industry. The findings suggest that future earnings changes vary systematically cross-sectionally as a function of risk, size and determinants of expected returns. Last, the findings suggest poor power of the tests when the stores and chemical industries are aggregated. "However, if a general model is not a good representation for all firms ( to the extent to which different characteristics generate future earnings in different firms in different ways ), we again introduce a conservative bias to the tests" [Ou and Penman (1989a), p. 299].

Overall the findings are in accordance with Greig (1992) who argues that the economic factors are causing the information link between the financial statement numbers and future earnings changes.

[^22]
## CHAPTER FIVE

Is Financial Statement Information About Future Earnings Changes Impounded In Current Stock Returns?

Evidence For The U.K.

### 5.1 INTRODUCTION

In chapters 3 and 4, evidence suggests that the annual financial statement numbers contain information concerning the sign and size of earnings changes one-year ahead. The objective of this chapter is to examine whether the market seems aware of the full implications of current financial accounting information for predicting future earnings changes. Specifically, an investigation is carried out to examine whether financial statement information concerning future earnings changes is impounded in this year's returns or next year's returns [the lagged impounding phenomenon as reported by Ou and Penman (1989a) for the U.S.A market] for the U.K market.

OP extending the prior work of McKibben (1972) argue that the market does not fully exploit financial statement information when predicting earnings (and returns). Their empirical results suggest that their Pr strategy generates abnormal returns up to 36 months after the financial statement items required to calculate $\operatorname{Pr}$ are available. The OP hypothesis is closely related to earlier postannouncement drift studies, which show that their income variables can predict stock returns. For example, Ball and Brown (1968) and Foster (1974) are the first to note that even after earnings announcements, estimated abnormal returns are predictable based on previously announced earnings. Freeman and Tse (1989) and Bernard and Thomas $(1989,1990)$ among others, confirm that the market underestimates the implications of previous earnings for future earnings.

The chapter is organised as follows. Section 5.2 explains the experimental design; Section 5.3 describes the hypotheses tested; section 5.4 the econometric issues; section 5.5 comments on the empirical results while 5.6 contains the conclusion.

### 5.2 EXPERIMENTAL DESIGN

A regression methodology, similar to that of Greig (1992), is adopted in this analysis: regression with individual firm-years observations as the unit of observation. Ou and Penman methodology of construction of portfolios was dropped for various reasons
(as explained shortly afterwards).
There are several advantages to using firm-year observations. First, it provides an alternative test to the relation between $\operatorname{Pr}_{\mathrm{it}}$ and stock returns independent of portfolios. Lo and MacKinlay (1991) and Larcker (1989) discuss the possible biases in statistical tests that arise when testing the relation using portfolios. Lys and Sabino (1991) also examine the choice between using portfolios and individual observations as alternative research methods. Ou and Penman themselves, pointed out that the portfolio grouping has the potential to inflate the rank-order correlations, relative to the rank-order correlations that would be observed if all of the observations were treated individually. It is unclear why portfolios are used in the OP analyses and what impact this procedure has on the econometric properties of the statistical tests. Some possible explanation might be that the portfolio grouping is the approach commonly used by prior researchers. In the OP paper, the cross-sectional analyses in table 2 as well as tables 5, 6 and 7, are based on rank-order correlations where the total sample of firms is collapsed into ten portfolios that are decreasing in the value of $\operatorname{Pr}$ i.e portfolio 1 consists of all firms in a given year with $\operatorname{Pr}$ values between 0.90 and 1.00 and portfolio 10 consists of all firms in a given year with $\operatorname{Pr}$ values between 0.00 and 0.10 . The median value of $\operatorname{Pr}$ within each of these ten portfolios is used as the observation value for $\operatorname{Pr}$. The median value for percentage change in one-step-ahead earnings for the firms in each portfolio is used as the observation for the one-stepahead earnings. The grouping method used by OP may cause the most extreme "measurement errors" in Pr to be forced into portfolios 1 and 10 . If the measurement errors in Pr are related to the measurement errors in the percentage change in one-step-ahead earnings, the correlations between the median values of these two measures will be inflated.

Second, using firm-year observations facilitates the introduction of additional and potential explanatory variables, especially size.

Third, the portfolio approach requires several arbitrary decisions. Should a single cutoff or multiple cutoffs be used? How are the cutoff points determined? Should the portfolios be based on absolute values or relative ranks? The use of
individual firm-year observations in a regression framework avoids these issues.
Finally, the use of a single regression using individual firm observations facilitates the decomposition of the relation between $\mathrm{Pr}_{\mathrm{it}}$ and subsequent stock returns into cross-sectional and cross-temporal effects.

### 5.3 HYPOTHESES TESTED

The Holthausen and Larcker approach is adopted by investigating the relationship between the accounting descriptors and stock returns directly. This contrasts with OP in which the descriptors generate values of Pr , which in turn are used to form an investment strategy. The rationale for this is that the OP experimental design is based on generating superior investment performance from buying (selling) those stocks where the earnings are predicted to increase (decrease). The motivation here is slightly different. It examines whether there is lagged impounding; that is whether investors underreact to financial statement information. Since the descriptor is the information that investors receive, then it seems sensible to focus on this variable in the analysis.

The Greig regression estimation is followed instead of constructing porfolios. Regression models using firm-year observations given in the following equations are used.

$$
\begin{align*}
& \text { Change }_{1, t+1}=a_{0}+a_{1} x_{1, j, t}+a_{3} R_{1, t}+e_{1, t} \\
& \text { Change }_{1, t+1}=a_{4}+a_{5} x_{1, j, t}+a_{6} R_{1, t+1}+e_{1, t} \tag{5.2}
\end{align*}
$$

where
Change $_{\mathrm{i}, \mathrm{i}+1}=$ the percentage change in earnings per share (prior to extraordinary items) for company $i$, between year $t$ and year $t+1$.
$\mathrm{R}_{\mathrm{i}, \mathrm{t}}=\quad$ the proportionate change in share price for company i , between 3 months after the year end $t-1$ and 3 months after the year end $t$.

The general advantages of using firm year observations over portfolio construction are well documented [refer to the previous section].

However, there are particular advantages which are relevant to the investigation of lagged impounding. The first advantage is that the method is well suited to the main issue of whether accounting descriptors contain information about earnings change which is not already captured by returns.

Secondly, it seems to be a way of dealing with Greig criticism of OP. The essence of this is that the variation in the descriptors ( $\mathrm{X}_{\mathrm{i}, \mathrm{t},}$ ) around the all industry average is likely to be associated with industry characteristics, including risk; however, industry risk differences will also be reflected in the variation of returns $\left(\mathrm{R}_{\mathrm{i}, \mathrm{t}}\right.$ and R $\mathrm{i}, \mathrm{t}+1$ ). In this context, therefore, the advantage of using regression is that it estimates the impact of each descriptor, conditional on the relationship between returns and changes in earnings per share. Therefore, if the variation in a descriptor does pick up industry characteristics which relate to risk, then the descriptor is unlikely to be significant with returns included in the equation. This discussion also extends to risk differences within industries, which impact on the descriptors.

In addition, what really matters is not the covariation of $X$ with $R$, but how relate to the change in earnings per share. Greig's criticism makes the assumption that the characteristics which partition industry groupings are also those which contain information about earnings change. The regression framework deals with this by assessing the marginal impact of the descriptor in predicting changes in earnings, over and above the information contained in returns.

The contribution of a descriptor to the prediction of the earnings change can be evaluated by the values of the coefficients in equations 5.1 and 5.2. One scenario is that $a_{1}=0$. In this case, then the information contained in the descriptor concerning the future change in profit is captured in contemporaneous returns; that is, the descriptor does not provide explanatory power about future profits over and above contemporaneous returns. This is the case when the market is efficient with respect to the information; in addition, $\mathrm{a}_{2}$ is likely to be significant since the Beaver, Lambert and Ryan (1987) evidence suggests that returns contain information about future
profits.
A second possibility is that $a_{1} \neq 0, a_{4}=0$ and $a_{5} \neq 0$. In this case, the descriptor contains information that is not captured in contemporaneous returns, but is captured in next period's returns. This is the case of lagged impounding. The coefficient a is likely to be significant as suggested above ${ }^{1}$.

A third and more ambiguous situation, "other effects", is when $a_{1} \neq 0$ and $a_{4}=0$. In this case, the infromation contained in the descriptor is not impounded in contemporaneous nor when the earnings is announced. The market efficiency explanation for this is about transitory earnings and therefore the effect may not be sufficiently large to be detectable in the returns. The alternative explanation is that there is lagged impounding of the descriptor in the first period and of earnings in the second

### 5.4 EMPIRICAL RESULTS

## Stores and Chemical Industries Together

## 1980-1988 PERIOD

To examine whether the accounting descriptors' information concerning the direction and sign of the future earnings changes is impounded in this year's or next year's stock returns, each descriptor is included with the this year's return and next year's return in a univariate regression model.

The appendix to this chapter, table A1 presents the coefficient estimates for all 83 accounting descriptors for the period 1980-88, along with a $t$-statistic (and p-value) relevant for the EMH $\mathrm{H}_{0}$ that the coefficient is zero and for the OP hypothesis $\mathrm{H}_{1}$ that

[^23]the coefficient is not zero at $10 \%$ significance level.
The majority of the financial statement variable indicate that the accounting descriptors' information concerning the sign and size of future earnings changes is reflected in this year's stock returns, thus supporting the maintained hypothesis of market efficiency, that all information is impounded instantaneously in current stock returns once the financial reports are made publicly available.

None of the findings support the OP hypothesis; that is, that the accounting descriptors' information concerning the sign and size of future earnings changes is reflected in next year's stock returns.

However, the findings suggest that some accounting descriptors's information concerning the sign and size of future earnings changes, for example, the $\% \Delta$ sales, the $\% \Delta$ debt/equity, the $\% \Delta$ operating profit/sales, the $\% \Delta$ working capital/total assets and the $\Delta$ total assets variables, is partly reflected in this year's stock returns and fully in next year's return.

The evidence also reveals that the information about future earnings sign and size contained by some accounting descriptors is neither reflected in this year's stock returns nor in next year's returns. Perhaps further tests extending to the information reflected in the stock returns two year's ahead might show whether the financial statement information is fully reflected in stock returns. The accounting variables exhibiting information beyond one year ahead, are the $\% \Delta$ inventory/total assets, the return on opening equity, return on closing equity, the $\% \Delta$ funds. These accounting descriptors are labelled on the table A1 [see appendix to this chapter] as "other" effects.

## 1980-1984 PERIOD

Throughout the period 1980-84, the findings suggest that the information concerning the sign and size of future earnings changes, contained by most of the accounting descriptors is impounded in this year's stock returns. Only three accounting descriptors' information about future earnings is not reflected in this year's stock
returns but in next year's returns. The three accounting descriptors exhibiting this informational characteristic are the $\% \Delta$ debtors, the $\% \Delta$ sales and the $\Delta$ sales/working capital variables. Evidence also suggests that the information about future earnings changes contained in some accounting descriptors is neither impounded in this year's nor next year's stock returns. These cases are labelled as "others". The results are shown in table 5.1.

Table 5.1 Multivariate Regression Estimation For The Stores and Chemical Industries Together Examining Whether The Accounting Descriptors' Information About Future Earnings' Sign and Size Changes Is Impounded In This Year's Or Next Year's Stock Returns Throughout The Period 1980-84.

## Stores Industry

## 1980-1988 PERIOD

To examine whether the accounting descriptors' information concerning the direction and sign of the future earnings changes is impounded in this year's or next year's stock returns, each descriptor is included with the this year's return and next year's return in a univariate regression model.

The appendix to this chapter, table A2 presents the coefficient estimates for all 83 accounting descriptors for the period 1980-88, along with a $t$-statistic (and p-value) relevant for the EMH $\mathrm{H}_{0}$ that the coefficient is zero and for the OP hypothesis $\mathrm{H}_{1}$ that the coefficient is not zero at $10 \%$ significance level.

The majority of the financial statement variable indicate that the accounting descriptors' information concerning the sign and size of future earnings changes is reflected in this year's stock returns, thus supporting the maintained hypothesis of market efficiency, that all information is impounded instantaneously in current stock returns once the financial reports are made publicly available.

The findings also suggest that the information about future earnings sign and size contained by some accounting descriptors is neither reflected in this year's stock returns nor in next year's returns. Perhaps further tests extending to the information reflected in the stock returns two year's ahead might show whether the financial statement information is fully reflected in stock returns. These are reported as "other" cases.

## 1980-1984 PERIOD

To examine whether the accounting descriptors' information concerning the direction and sign of the future earnings changes is impounded in this year's or next year's stock returns, each descriptor is included with the this year's return and next year's return in a univariate regression model.

The majority of the financial statement variable indicate that the accounting descriptors' information concerning the sign and size of future earnings changes is reflected in this year's stock returns, thus supporting the maintained hypothesis of market efficiency, that all information is impounded instantaneously in current stock returns once the financial reports are made publicly available.

A number of the accounting descriptors however, indicate that the information they contain regarding future earnings changes is impounded in next year's stock returns. The accounting descriptors exhibiting this characteristic are the $\% \Delta$ sales, the depreciation/fixed assets, the $\Delta$ depreciation/fixed assets, the $\% \Delta$ sales/total assets, the $\Delta$ sales/cash and the $\% \Delta$ sales/inventory.

The findings also suggest that the information about future earnings sign and size contained by some accounting descriptors is neither reflected in this year's stock returns nor in next year's returns. Perhaps further tests extending to the information reflected in the stock returns two year's ahead might show whether the financial statement information is fully reflected in stock returns. These are referred as "other" cases. The accounting descriptors exhibiting this characteristic are the $\% \Delta$ dividend per share, $\Delta$ debt/equity, $\% \Delta$ debt/equity, the sales/working capital and the $\Delta$ working capital/total assets. The results are shown in table 5.6.

Table 5.6 Multivariate Regression Estimation For The Stores Industry Examining Whether The Accounting Descriptors Information About Future Earnings' Sign And Size Changes Is Impounded In This Year's Stock Returns Or In Next Year's Stock Returns Throughout The Period 1980-84.

$\mathbf{R}_{t}$ is this year's stock returns; $\mathbf{R}_{1+1}$ is next year's stock returns;

## CHEMICAL INDUSTRY

## 1980-1988 Period

To examine whether the accounting descriptors' information concerning the direction and sign of the future earnings changes is impounded in this year's or next year's stock returns, each descriptor is included with the this year's return and next year's return in a univariate regression model.

The appendix to this chapter, table A3 presents the coefficient estimates for all 83 accounting descriptors for the period 1980-88, along with a t-statistic (and p-value) relevant for the EMH $\mathrm{H}_{0}$ that the coefficient is zero and for the OP hypothesis $\mathrm{H}_{1}$ that the coefficient is not zero at $10 \%$ significance level.

The majority of the financial statement variable indicate that the accounting descriptors' information concerning the sign and size of future earnings changes is
reflected in this year's stock returns, thus supporting the maintained hypothesis of market efficiency, that all information is impounded instantaneously in current stock returns once the financial reports are made publicly available.

None of the findings support the OP hypothesis; that is, that the accounting descriptors' information concerning the sign and size of future earnings changes is reflected in next year's stock returns.

The evidence also reveals that the information about future earnings sign and size contained by some accounting descriptors is neither reflected in this year's stock returns nor in next year's returns. Perhaps further tests extending to the information reflected in the stock returns two year's ahead might show whether the financial statement information is fully reflected in stock returns. The accounting variables exhibiting information beyond one year ahead, are the quick assets ratio, $\Delta$ depreciaton/fixed assets, $\% \Delta$ capital expenditure/total assets and $\% \Delta$ net profit margin. These are referred as "other" effects.

## 1980-1984 PERIOD

The majority of the financial statement variable indicate that the accounting descriptors' information concerning the sign and size of future earnings changes is reflected in this year's stock returns, thus supporting the maintained hypothesis of market efficiency, that all information is impounded instantaneously in current stock returns once the financial reports are made publicly available.

None of the findings support the OP hypothesis; that is, that the accounting descriptors' information concerning the sign and size of future earnings changes is reflected in next year's stock returns.

The evidence also reveals that the information about future earnings sign and size contained by some accounting descriptors is neither reflected in this year's stock returns nor in next year's returns. Perhaps further tests extending to the information reflected in the stock returns two year's ahead might show whether the financial statement information is fully reflected in stock returns.

The results are shown in table 5.11.

a these are referred as "other effects" in the analysis. Theoretical explanations as provided by a number of studies [Stober (1992), Ball (1992)] are offered for these "other effects".
$\mathrm{a}_{0}$ is the constant of the accounting coefficients;
$X_{u}$ is the coefficient of the accounting descriptor;
$\mathrm{R}_{1}$ is this year's stock returns;
$R_{t+1}$ is next year's stock returns.

### 5.7 CONCLUDING REMARKS

This chapter investigates whether the financial statements numbers' information concerning the direction and size of earnings changes is impounded in the current year's stock return or in the following year's stock return. It provides empirical evidence of a relationship between the financial statements incremental information and stock returns.

## Stores and Chemical Industries together

The findings suggest that, in most cases, the financial statement numbers's information concerning the sign and size of future earnings changes is impounded in current stock returns throughout the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88. Thus the maintained hypothesis of market efficiency is supported by the findings.

However, there is a number of accounting descriptors indicating that the financial statement numbers' information is impounded in the following year's stock return, thus supporting the Ou and Penman hypothesis of a lagged impounding phenomenon. Throughout the period 1980-84, three accounting descriptors exhibit lagged impounding phenomenon. These variables are the $\% \Delta$ debtors ratio, the $\%$ $\Delta$ sales and the $\% \Delta$ return on opening equity. Throughout the period 1981-85, only one descriptor exhibits lagged impounding characteristics. This variable is the $\% \Delta$ uses variable. Throughout the period 1982-86, two descriptors exhibit lagged impounding characteristics: the two descriptors are the $\% \Delta$ return on opening equity and the return on total assets..

Last, the findings also suggest that some accounting descriptors' information about future earnings changes is neither impounded in current stock return nor in the following year's return. These are referred as "other effects" in the analysis carried out. Theoretical explanations as offered by a number of studies, for example Stober (1992), are offered. However, no empirical tests have been carried to test these "other
effects".

## Stores Industry

The findings suggest that, in most cases, financial statement numbers' information concerning the sign and size of future earnings changes is impounded in current stock returns throughout the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88. Thus the findings support the maintained hypothesis of market efficiency.

However, there is a number of accounting descriptors indicating that the financial statement numbers' information is impounded in the following year's stock return, thus supporting the Ou and Penman hypothesis. Throughout the period 198084, the accounting descriptors exhibiting this lagged impounding phenomenon are the $\% \Delta$ sales, the depreciation/fixed assets, the $\Delta$ depreciation/fixed assets, the $\% \Delta$ sales/total assets, the $\Delta$ sales/cash and the $\% \Delta$ sales/inventory variables. Throughout the period 1981-85, the sales/total assets and the $\Delta$ working capital/total assets variables exhibit lagged impounding characteristic while throughout the period 198286 , the $\Delta$ debtors ratio, the return on opening equity and the $\Delta$ working capital/total assets variables indicate that the information about future earnings changes is impounded in the following year's stock returns.

The findings also suggest that some accounting descriptors' information about future earnings changes is neither impounded in current stock returns nor in the following year's returns. These are referred as "other effects".

## Chemical Industry

The findings suggest that, in most cases, financial statement numbers' information concerning the sign and size of future earnings changes is impounded in current stock returns throughout the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88. The findings support the maintained hypothesis of market efficiency.

However, there is a number of accounting descriptors indicating that the
financial statement numbers' information is impounded in the following year's stock returns, thus supporting the Ou and Penman hypothesis. Throughout the period 198286, the accounting descriptors exhibiting this lagged impounding phenomenon are the $\Delta$ times interest earned and the $\% \Delta$ times interest earned. Throughout the period 1983-87, the times interest earned and the \% operating profit/sales variables exhibit lagged impounding characteristic.

The findings also suggest that some accounting descriptors' information about future earnings changes is neither impounded in current stock returns nor in the following year's returns. These are referred as "other effects".

## Concluding Remarks

The findings suggest that the information concerning future earnings changes contained by the financial statement numbers is impounded in the current stock return, in the majority of cases. There is, though, a number of accounting descriptors whose information concerning future earnings changes is impounded in the following year's stock return and not in the current. These findings support the OP hypothesis that there is indeed a lagged impounding phenomenon. However, there is a number of accounting descriptors whose information is neither reflected in the current year's stock return nor in the following year's stock return. These cases are labelled in the tables as "other effects". These "other effects" are not tested empirically in this thesis. Only theoretical explanations as offered by a number of studies, for example, Stober (1992) and Ball (1992), have been provided in this chapter. The rationale being that the main objective of the analysis is to establish whether there is a lagged impounding phenomenon; that is, a time lag of one year, in the market, before all accounting information is impounded in current prices.

## CHAPTER SIX

Is The Lagged Impounding Phenomenon Of Financial Statement Numbers Information About Future Earnings Changes Valid For Both The Positive and Negative Values Of The Earnings Changes? Evidence For The U.K.

### 6.1 INTRODUCTION

Evidence is chapter 5 suggests that the information concerning the direction and size of future earnings changes contained by some accounting descriptors, is indeed impounded in next year's stock returns.

The purpose of this chapter is to examine whether this lagged impounding phenomenon of financial statement report numbers is valid for only particular parts of the earnings changes. Specifically, an investigation is carried out to examine whether the lagged impounding phenomenon is valid for both negative and positive values of the $\% \Delta$ operating profit variable changes. This chapter provides empirical evidence of a valuation link between financial statement numbers' information and stock returns.

### 6.2 HYPOTHESES DEVELOPMENT

The lagged impounding of the market to negative news has been found in the activities of financial analysts. McNichols (1988) finds that security return prediction errors are less positively skewed in earnings announcement periods than in nonannouncement periods. She suggests that this might be due to that bad news is reflected less rapidly in prices because managers tend to disclose bad news earnings less rapidly than good news.

In recent capital market research, analysts forecasts tend to be optimistic on average, that is, they appear to overestimate future earnings, and stock prices underreact to earnings announcements and the subsequent completion of the reaction appears in the form of a "post-earnings announcement drift" in stock prices.

Freeman and Tse (1989) and Bernard and Thomas[BT] (1990) present evidence that the market underestimates the implications of previous period earnings for future earnings. Transaction costs have been ruled out as a possible explanation for the "drift" in BT $(1989,1990)$ and Ball (1992) but Bushan (1994) argues that transactions
costs in conjunction with differing abilities among investors to process information, can result in post-announcement drift.

Lys and Sohn argue that analysts' forecasts are based on information partly independent across analysts and partly independent of corporate disclosures. Both Abarbanell (1991) and Klein (1990) confirm the Lys and Sohn results. Moreover, the "herding" behaviour explained by Truemann (1994) that analysts have rather share mistakes with other analysts rather than borne mistakes on their own, might offer a second explanation for the drift.

In research which investigates the potential links between analysts forecasting behaviour and post-earnings announcement drifts, Mendenhall (1991), Abarbanell and Bernard (1991) and Ali, Klein and Rosenfeld (1992) find that analysts underestimate the persistence of past earnings forecasts errors in forecasting future earnings, that is, analysts do not utilize time-series information about earnings correctly when setting their forecasts. On the other hand, DeBondt and Thaler $(1987,1990)$ characterise their evidence as consistent with overreaction to earnings and suggest that corrections of such overreactions may explain the long-term reversals of extreme prior stock price changes documented by DeBondt and Thaler (1985) and Chopra, Lakonishok and Ritter (1992).

Repeated attempts to explain post-earnings announcement drift as the product of research design flaws including a failure to fully control for risk, have failed to resolve the anomaly.

Bernard and Thomas $(1989,1990)$ investigate the hypothesis that stock prices partially reflect a naive earnings expectation: that future earnings will be equal to earnings for the comparable quarter for the prior year. It is well known that forecast errors on such a naive model [Fried and Givoly(1982)] are correlated through time. In contrast, in a market that fully impounds all prior earnings information, forecast errors should not be autocorrelated. Mendenhall (1991) finds evidence of positive serial correlation in Value Line earnings forecasts errors as well as a positive relation between forecast revisions and returns around the subsequent earnings announcements. He interprets his results as indicating analysts underreaction to earnings information
in forming their forecasts. Abarbanell and Bernard (1991) using Value Line earnings forecasts (where relatively precise dating is possible) find that forecast extremes are eliminated after the first quarter. In addition, the most optimistic earnings forecasts (biggest overestimates) are associated with firms with weak earnings performance the previous year. He concludes that analysts appear to underreact to past earnings signals. Ali, Klein and Rosenfeld (1992) find a significant positive serial correlation in eightmonth and one-month forecast errors, result consistent with the hypothesis that analysts on average underestimate the permanence of the last year's forecast error when setting forecasts. Further, they find an overprediction bias for both forecast horizons. The over prediction bias is most pronounced for firms previously having reported negative annual earnings. Also, the positive serial correlation in the prediction errors is greatest form firms with previous period earnings predominantly permanent.

DeBondt and Thaler $(1985,1987)$ show that mean reversion in stock prices is evidence of overreaction. DeBondt and Thaler (1985) show that stocks that were extreme "losers" over an initial three-to five year period earned excess returns over the subsequent three to five years. In the 1987 paper, it was shown that these excess returns cannot easily be attributed to changes in risk, tax or the small firm effects. Rather these excess returns to losers might be explained by biased expectations of the future: earnings for losing firms had fallen precipitously during the formation period but then rebounded strongly over the next few years i.e the market participants may overreact to current earnings not recognising that extreme annual earnings changes tend to be partially reversed in the future. Ball and Kothari (1989) suggest that when one controls for nonstationary betas the market-adjusted returns can be explained as risk premia. However, Chopra, Lakonishok and Ritter (1992) argue that Ball and Kothari[1989] rely on the Sharpe-Lintner CAPM and the influence of the beta adjustment might be overstated while if used the market price of risks the DeBondt and Thaler portfolios generate abnormal returns of approximately $5 \%$ per year even after controlling for nonstationary betas and the size effect. DeBondt and Thaler (1990) report evidence suggesting that analysts's earnings forecasts tracked by Institutional Brokers Estimate System (IBES) are indeed "consistent with generalized
overreaction". Specifically, they show that earnings changes forecasted by analysts are significantly more extreme than actual realizations and conclude that the forecasts are "simply too extreme to be considered rational". Klein (1990) motivated by the cognitive bias theory put forward by DeBondt and Thaler (1987, 1990), tests whether analysts systematically underpredict earnings following large share price declines and overpredict earnings after large price increases, and finds no evidence that they do. The evidence instead supports nonsymmetric forecasting behaviour: forecasts after price declines are optimistic i.e forecasts exceeding the actual earnings, and forecasts after price increases are neither optimistic nor pessimistic i.e there is no particular bias in the forecast errors. Results more consistent with the underreaction not the overreaction that DeBondt and Thaler find.

The literature on both underreaction and overreaction indicates that the anomalous stock price behaviour around earnings announcements may be due to a failure by market participants to appreciate what current earnings imply about future earnings.

### 6.3 EXPERIMENTAL DESIGN

The data sample used for the tests carried out in this chapter, for the Stores industry, are sub-divided into three sub-periods ${ }^{1}: 1980-84,1981-85,1982-86$, and for Chemical industry, into two sub-periods ${ }^{2}$ : 1982-86, 1983-87.

To examine whether the lagged impounding phenomenon documented for some financial statement numbers is only valid for negative and/or positive values of the \% $\Delta$ operating profit, the analysis is carried out in three stages: in the first stage, each accounting descriptor is included as the sole explanatory variable in a univariate regression analysis; in the second stage, each accounting descriptor is included with this year's stock returns in a multivariate regression analysis; in the third stage, each

[^26]accounting descriptor is included with next year's stock returns in a multivariate regression.

The dependent variable is defined as the $\% \Delta$ Operating profit $=\mathrm{OP}_{\mathrm{t}}-\mathrm{OP}_{\mathrm{t}-1} / \mathrm{OP}_{\mathrm{t}-1}$. and is specified in two ways: first, it takes only the negative values and is regressed on the relevant accounting variable, this year's stock returns and then next year's stock returns;
second, it takes only the positive values and is regressed on the relevant accounting descriptor, this year's stock returns and then next year's stock returns.

The analysis is carried out for stores and chemical industries separately. The rationale is that analysts might follow one particular industry more than another; for example, the stores industry might be followed by more analysts than the chemical industry.

The following three equations are estimated for the purpose of this analysis:

$$
\begin{equation*}
\% \text { soperatingprofitit+1 }=a_{0}+a_{1} X_{i t}+u_{i t} \tag{6.1}
\end{equation*}
$$

where $\mathrm{x}_{\mathrm{it}}$ is the accounting descriptor and $\mathrm{e}_{\mathrm{it}}$ is the error term. The EMH accepts that $a_{1}=0$; that is, accounting descriptors do not contain information about future earnings sign and size changes. The OP hypothesis accepts that $\mathrm{a}_{1} \neq 0$. This hypothesis supports that accounting descriptors contain information about future earnings changes.

$$
\begin{equation*}
\% \Delta \text { operatingprofit } t_{i t+1}=a_{3}+a_{4} X_{i t}+a_{5} R_{t}+e_{i t} \tag{6.2}
\end{equation*}
$$

where $x_{i t}$ is the accounting descriptor and $R_{t}$ is this year's stock returns.
The EMH accepts that $a_{4} \neq 0$ while $a_{5}=0$. The null hypothesis suggests that the accounting descriptors' information about future earnings changes is reflected in current stock returns. The OP hypothesis supports that the accounting information concerning the sign and size of future earnings changes is not impounded in this year's stock returns.

$$
\begin{equation*}
\% \Delta \text { operatingprofit } t_{t+1}=a_{6}+a_{7} X_{i t}+a_{8} R_{t+1}+u_{i t} \tag{6.3}
\end{equation*}
$$

where $R_{t+1}$ is next year's stock returns. The EMH accepts that $a_{7}=0$ while $a_{8}=0$. The null hypothesis accepts that the accounting descriptors' information about future earnings changes is reflected in next year's stock returns. The OP hypothesis also accepts that accounting descriptors' information is impounded in next year's stock returns.

However, the $R_{t}$ and $R_{t+1}$ in equations 6.2 and 6.3 respectively, might be merely reflecting underlying technical relationships that these returns are capturing. In other words, the current returns and next year returns might be reflecting changes in, for example, decrease/increase in production costs, and not explicitly the information contained by financial statement variables.

### 6.4 EMPIRICAL RESULTS

## Stores Industry

## 1980-1984 Period

I examine whether the accounting descriptors exhibit information about future earnings'sign and size changes and whether this ability of the accounting descriptors is only valid for the negative and/or particular values of the $\% \Delta$ operating profit. The findings suggest that during the period 1980-84, the $\% \Delta$ sales, the $\Delta$ depreciation/fixed assets, the $\% \Delta$ sales/total assets, the $\Delta$ sales/cash, the $\% \Delta$ sales./inventory, the $\Delta$ working capital/total assets and the $\% \Delta$ working capital/total assets variables, all exhibit information about future earnings changes valid for the negative and/or positive values of the earnings changes. The results are shown in table 6.1.

Table 6.1: Multivariate Regression Analysis Examining Whether The Accounting Descriptor's Ability To Contain Information About Future Earnings Changes Is Valid Only For The Positive And/Or Negative Values Of The \% $\Delta$ Operating profit During The Period 1980-1984.

## $\% \Delta$ operating profit has a negative distribution

## $\% \Delta$ sales

The $\% \Delta$ in sales contains information about future earnings' sign and size changes. This informational characteristic is only valid for the negative distribution of the $\% \Delta$ in operating profit descriptor. This information the $\% \Delta$ in sales contains about future earnings changes is not reflected in the current stock returns, but part of this information is reflected in next year's stock returns.

The $\% \Delta$ sales descriptor exhibits a negative relationship with the $\% \Delta$ operating profit variable. However, the $\% \Delta$ sales variable does not account for the cost of the goods sold and it might refer to firms financing their working capital requirements through debt. This conclusion is further supported by the negative relationship, the $\Delta$
working capital/total assets and the $\% \Delta$ working capital/total assets variables exhibit with the $\% \Delta$ in operating profit. Moreover, the constant of the coefficient is statistically significant, indicating that economic circumstances in this period are more important than the information about future earnings changes contained in the financial statements.

## $\Delta$ working capital/total assets and $\% \Delta$ working capital/total assets

The $\Delta$ working capital and the $\% \Delta$ working capital descriptors contain information about future earnings' sign and size changes. This informational characteristic the $\Delta$ and the $\% \Delta$ working capital/total assets variables exhibit is only valid for the negative distribution of the $\% \Delta$ operating profit variable. However, this information about future earnings changes is not reflected in current stock returns, but only part of this information is reflected in next year's stock returns. This result might be further supported by Stober (1992) who finds that the "Pr" measure of OP is just a proxy for expected returns.

The $\Delta$ and the $\% \Delta$ working capital/total assets variables exhibit a negative relationship with the $\% \Delta$ operating profit variable. This might indicate that companies have large volume of stocks and debtors. This will result in over-investing in working capital and so tying up more funds in the business than it needs to. This might also suggest poor management of debtors (credit).

## $\Delta$ sales/cash

The $\Delta$ sales/cash descriptor exhibits information about future earnings' sign and size changes. The informational characteristic this accounting descriptor exhibits is only valid for the negative values the $\% \Delta$ operating profit variable. Moreover, the $\Delta$ sales/cash exhibits information about future earnings changes only when regressed with next year's stock returns. No reasonable explanation can be provided.

## \% $\Delta$ operating profit has a positive distribution

## $\Delta$ depreciation/fixed assets

The $\Delta$ depreciation/fixed assets variable does not have any information about the future earnings changes in the univariate regression, but when, regressed with this year's stock returns and next year's returns, is having information about the future earnings changes. However, this information is neither reflected in the current stock returns nor in next year's stock returns. I am unable to provide any reasonable explanation for this result.

## $\% \Delta$ sales/inventory

The $\% \Delta$ sales/inventory variable contains information about future earnings changes and this information is reflected in this year's stock returns. However, a further test shows that the $\% \Delta$ sales/inventory variable still contains information which is not reflected in next year's stock returns. Again, I am unable to provide any reasonable explanation for this result.

## $\Delta$ working capital/total assets, $\% \Delta$ working capital/total assets

The $\Delta$ working capital/total assets and the $\% \Delta$ working capital/total assets variables do not have any information about the future earnings changes in the univariate regression, but when, regressed with this year's stock returns and next year's stock returns are having information about the future earnings changes. This information is neither reflected in this year's stock returns nor in next year's stock returns. I am unable to provide any reasonable explanation for this result.

## 1981-1985 Period

I examine whether the accounting descriptors exhibit information about future earnings'sign and size changes and whether this ability of the accounting descriptors is only valid for the negative and/or particular values of the $\% \Delta$ operating profit. The findings suggest that during the period 1981-85, the $\Delta$ working capital/total assets variable exhibits information about future earnings' sign and size changes. The results are shown in 6.2.

Table 6.2 Multivariate Regression Analysis Examining Whether The Accounting Descriptor's Ability To Contain Information About Future Earnings' Sign And Size Changes Is Valid Only For The Negative And/Or Positive Values Of The \% $\Delta$ Operating Profit During The Period 1981-1985.

## $\% \Delta$ operating profit has a positive distribution

## $\Delta$ times interest earned

The $\Delta$ times interest earned descriptor does not exhibit information about future earnings changes in the univariate regression, but when, regressed with this, it exhibits information about the future earnings changes. However, this information is neither reflected in this year's stock returns nor in next year's stock returns. I am unable to provide any reasonable explanation for this result.

### 6.5 CONCLUDING REMARKS

This chapter examines whether the lagged impounding phenomenon of financial statement report numbers is valid for both negative and positive values of the $\% \Delta$ operating profit variable changes. It provides empirical evidence of a valuation relationship between financial statement numbers' information and stock returns for the stores and chemical industries.

## Stores Industry

During the period $1980-84$, the findings suggest that the $\% \Delta$ sales, the $\Delta$ working capital/total assets and the $\% \Delta$ working capital/total assets variables exhibit information concerning the direction and size of future earnings changes. The information exhibited by these variables is valid only for the negative values of the $\% \Delta$ operating profit variable changes.

Moreover, the constant of the accounting coefficient is statistically significant, indicating that economic circumstances during this period are more important than the information about future earnings changes contained in the financial statements report numbers.

During the 1980-84 period, the findings also reveal a lagged impounding phenomenon [as reported by Ou and Penman (1989a)] valid only for the positive values of the $\% \Delta$ operating profit variable. The accounting variable exhibiting this lagged impounding phenomenon is the $\% \Delta$ sales/inventory variable. During the same period 1980-84, another three accounting variables, the $\Delta$ depreciation/fixed assets, the $\Delta$ working capital/total assets and the $\% \Delta$ working capital/total assets, exhibit information concerning future earnings changes. These accounting descriptors' ability to exhibit information is only valid for the positive values of the earnings changes. However, they exhibit this informational characteristic only when they are regressed with the current year's stock returns and the following year's stock returns in a multivariate regression model. No theoretical explanation can be offered for the predictive ability of these accounting descriptors.

During the period 1981-85, the $\Delta$ working capital/total assets variable exhibits information concerning future earnings' sign and size changes. This accounting descriptor's ability to describe future earnings changes is only valid for the positive values of the $\% \Delta$ operating profit variable. But what is more amazing, it is that this accounting descriptor predicts future earnings changes only when regressed with this year's and next year's stock returns in a multivariate regression model. Again, no theoretical explanation can be offered for the predictive ability of this accounting descriptor.

## Chemical Industry

During the period 1982-86, the times interest earned and the $\Delta$ times interest earned exhibit information concerning future earnings' sign and size changes. This accounting descriptor's ability to describe future earnings changes is only valid for the positive values of the $\% \Delta$ operating profit variable. But what is more amazing, it is that these accounting descriptors predict future earnings changes only when regressed with this year's and next year's stock returns in a multivariate regression model.

Moreover, the constant of the accounting coefficient is statistically significant, indicating that economic circumstances during this period are more important than the information about future earnings changes contained in the financial statements report numbers.

During the period 1983-87, the times interest earned and the $\% \Delta$ operating profit/sales exhibit information concerning future earnings' sign and size changes. These accounting descriptor's ability to describe future earnings changes is only valid for the positive values of the $\% \Delta$ operating profit variable. However, these accounting descriptors predict future earnings changes only when regressed with this year's and next year's stock returns in a multivariate regression model.

## Concluding Remarks

The findings suggest that for the stores industry, during the period 1980-84, only in the case of the $\% \Delta$ sales variable, there exists clear evidence that the ability of the $\% \Delta$ sales variable to predict future earnings' sign and size changes is valid only for the negative values of the $\% \Delta$ operating profit variable. Also, the findings reveal that the $\% \Delta$ sales/inventory variable exhibits a lagged impounding phenomenon as reported by Ou and Penman (1989a). This lagged impounding phenomenon is valid only for the positive values of the $\% \Delta$ operating profit variable.

The rest of the evidence presented for the stores industry during the periods 1980-84, 1981-85 and 1982-86 is spurious. The accounting descriptors exhibit information concerning the sign and size of earnings changes only when regressed with the current year's stock return and the following year's stock return.

For the chemical industry, the findings present spurious evidence as well. The accounting descriptors exhibit information concerning the sign and size of earnings changes only when regressed with the current year's stock return and the following year's stock return.

Possible explanations for the results might lie in the activities of analysts. For example, analysts engaged in forecasting might be subjected to psychological forces
[Kahneman and Tversky (1975)], or to the "herding" behaviour [Truemann (1994)] or to other personal incentives, like for example, analysts release forecasts similar to those previously announced by other analysts, even when this is not justified by their information.

A second explanation of why the information is not reflected in this year's stock returns might be the transaction costs (Bushan 1994). Transactions costs are also inversely related to firm size.

## CHAPTER SEVEN

Is The Lagged Impounding Phenomenon Of Financial Statement Numbers Information About Future Earnings Changes Driven By Large Or Small Companies? Evidence for the U.K.

### 7.1 INTRODUCTION AND HYPOTHESES DEVELOPMENT

Annual financial statements report numbers' information about the direction and size of future earnings changes is impounded in next year's stock returns. The purpose of this chapter is to examine whether the lagged impounding phenomenon is attributed to the way the market process information. Specifically, an investigation is carried out to examine whether the information about future earnings changes is reflected quicker in the current share prices for large companies and later for small companies.

The "firm size effect" is one area where a growing stream of evidence has arisen to suggest an apparent inefficiency. Greig (1992) argues that Ou and Penman Pr measure "works in the sense of predicting future returns because it is a proxy for expected returns associated with differences in relative size and not because it captures abnormal returns associated with stock price deviations from fundamental values".

In a well publicized study, Bantz (1981) finds that the stocks of small NYSE firms earned higher risk-adjusted returns than the stocks of large NYSE firms. Bantz finds a negative association between average returns to stocks and the market value of the stocks after controlling for risk.

This empirical finding prompted a number of researchers, amongst those, Reinganum (1981) to see whether there is any interrelationship between the "size effect" and other empirical anomalies apparent in stock return data. Reinganum[1981) using a sample of both NYSE and Amex firms, finds abnormally large risk-adjusted returns for small firms. Specifically, Reinganum concludes: "after controlling returns for any P/E effect, a strong firm size effect still emerged. But after controlling returns for any market value effect, a separate P/E effect was not found". Reinganum's conclusion is that the "size effect" subsumes Basu (1977) evidence that stocks with high earnings/price ( $\mathrm{E} / \mathrm{P}$ ) ratios have higher average risk-adjusted returns than low $\mathrm{E} / \mathrm{P}$ stocks. However, both Bantz (1981) and Reinganum (1981) attributed the results to a misspecification of the CAPM rather than inefficiency, unwilling to reject the idea that the market could have inefficiencies of this type.

The papers by Bantz (1981) and Reinganum (1981) have drawn a lot of
attention and a number of papers have analyzed the statistical tests used in these two papers. According to Schwert (1983) papers trying to analyze "size effect" fall into tree categories: [1] "papers that look for an explanation of the findings of Bantz (1981a) and Reinganum (1981) in measurement of statistical testing errors; [2] papers that provide more detailed characterization of the "size effect"; and [3] papers that propose an economic explanation of the evidence."

In the first group of "size effect" as a statistical artifact, Roll (1981) argues that the stocks of small firms are traded less frequently than those of large firms, thus estimates of systematic risk from daily stock returns will be biased downward. However "both Roll and Reinganum (1982) conclude that the bias in risk estimates due to non-synchronous trading cannot explain the magnitude of the risk-adjusted returns found by Reinganum (1981a).

Christie and Hertzel (1981) argue that the "size effect" could be due to nonstationarity in the risk measures. The risk of the stock of a levered firm increases as the stock value decreases. Assuming risk is constant over time, the risk of levered stocks whose value has fallen, is understated; hence, average risk-adjusted returns for stocks with low current value should be positive because risk is underestimated. However, Christie and Hertzel (1981) even adjusting for this bias in risk estimates still find that "size effect" exists.

In 1983, Basu re-examines Reinganum's (1981a) results using both different sample period and different way for forming portfolios of stocks on both size and earnings/price ratios. Basu (1983) results contradict Reinganum's (1981a) conclusion that the "size effect" subsumes the E/P effect. He argues that there is indeed some interaction between size and $\mathrm{E} / \mathrm{P}$ ratios: the magnitude of risk-adjusted returns is largest for small firms with high E/P ratios.

Roll (1982) and Blume and Stambaugh (1983) find that the magnitude of the "size effect" is sensitive to the technique used to calculate average risk-adjusted returns and thus question the empirical importance of the "size effect".

In the second group, having observed that small firms have higher returns than large firms and that returns in January are higher than in any other month of the year,

Keim (1983) examining all NYSE-listed and AMEX-listed stocks over the 17-year period of 1963 to 1979 and forming ten portfolios based on size with portfolio 1 containing the smallest $10 \%$ of the firms, portfolio number 2 containing the next smallest $10 \%$ and so on, finds that the January effect has been due primarily to the behaviour of small firms and the size effect has been concentrated mainly in the month of January. Further examination of this interrelationship between the size effect and the January effect has shown that it is concentrated in the first five trading days in January.

Brown, Kleidon and Marsh (1983) examine the behaviour of "size effect" over time. They find that the risk-adjusted average returns to portfolios ranked on size are linearly related to the size variable but the magnitude and sign of the relation is not constant throughout the sample period 1967-79: a negative excess return between 1969-73 for small stocks and a positive excess return for the period 1974-79.

Attempts to explain this interrelationship between the "January effect" and the "size effect" appearing to have some merit have to do with "tax selling" [Roll(1977), Reinganum(1983), Lakonishok and Smidt(1986)].

Keim and Stambaugh (1984) extend the previously mentioned studies of the day-of-the-week effect back to 1928 and negative Monday returns were documented over the 55-year period. Using all NYSE-listed and AMEX-listed stocks for the 196379 period and forming ten size-based portfolios, Monday returns were observed for all sizes of portfolios. However, there was no systematic relationship between portfolio size and the size of the Monday return.

A second explanation is that small stocks may be relatively riskier in January, thus they should have a relatively higher average return in January. Two studies lending support to this argument are Rogalski and Tinic(1986) and Arbel(1985).

Other papers have examined the magnitude of transaction costs for stocks of firms in different size categories [Stoll and Whaley(1983) and Schultz(1983)]. Stoll and Whaley(1983) examining monthly returns of NYSE-listed stocks from 1960 to 1979 for ten portfolios ranked on market value of the stocks, find that small stocks tend to have lower prices and higher bid-ask spreads, so transaction costs are relatively
high for these stocks. They estimate risk-adjusted returns to the small firm portfolio net of transaction costs and find that a round-trip transaction every three months is sufficient to eliminate the "size effect". However, Schultz (1983) examining daily returns to NYSE-listed and AMEX-listed stocks from 1963 to 1979 finds similar results to those of Stoll and Whaley (1983). However, he also estimates average transaction costs for each month and finds no evidence of seasonality that could explain the "January size effect" found by Keim (1983). Schultz conclusion is that transaction costs cannot explain the high average returns to small firms' stocks.

### 7.2 EXPERIMENTAL DESIGN

The information accounting descriptors contain about future earnings changes, is impounded in next year's stock returns.

In order to test whether the lagged impounding phenomenon as documented in chapter 5 is indeed due to large or small companies, two issues are tested.

- Is the financial statement information concerning the direction and size changes of future earnings is impounded in next year's stock returns for small companies.
- Is the financial statement information concerning the direction and size changes of future earnings is impounded in next year's stock returns for large companies.

$$
\begin{equation*}
\% \Delta \text { operatingprofit }=a_{0}+a_{1} x_{1}+a_{2} R_{t}+a_{3} D+e_{i t} \tag{7.1}
\end{equation*}
$$

where $x_{i}$ represents the accounting descriptor, $R_{1}$ represents this year's stock returns and D the dummy variable.

The sales variable, in $\log$ form, is used as a proxy for size. The dummy variable is specified, using the MEAN of the log of sales variable, in two ways: A. - if observations are greater than the MEAN, then the dummy variable takes the value of 0 , and this signifies large companies.

- if observations are smaller than the MEAN, then the dummy variable takes the value of this year's returns.
B. $\quad$ if observations are greater than the MEAN, then the dummy variable takes the value of 0 , and this signifies large companies.
- if observations are smaller than the MEAN, then the dummy variable takes the value of next year's returns.

The Efficient Market Hypothesis accepts that $\mathrm{a}_{2}$ is statistically significant from zero while $a_{1}=a_{3}=0$. The OP hypothesis, if it is driven by small firms, accepts $a_{2}$ is statistically significant from zero while $a_{3}=-a_{2}$.

$$
\begin{equation*}
\% \Delta \text { operatingprofit }=a_{4}+a_{5} x_{1}+a_{6} R_{t+1}+a_{7} D+e_{1 t} \tag{7.2}
\end{equation*}
$$

where $x_{i}$ represents the accounting descriptor, $\mathrm{R}_{\mathrm{t}+1}$ represents next year's stock returns and $D$ the dummy variable. The EMH accepts that $a_{6}=a_{7}=0$ while the OP hypothesis, if it is driven by small firms, supports that for small companies $a_{6}=0$ and $a_{7} \neq 0$ [statistically significant from zero].

### 7.3 EMPIRICAL RESULTS

## Stores Industry

## 1980-1984 Period

To examine whether the lagged impounding phenomenon is valid for small or large companies or for both small and large companies, a multivariate regression model is run. During the period $1980-84$, the findings suggest that the lagged impounding phenomenon is valid for LARGE companies. The results are shown in table 7.1.

Table 7.1: Multivariate Regression Analysis For The Stores Industry For The Period 1980-84 Testing For The Effect Of Large and Small Companies On The Information Impounded In This Year's And Next Year's Stock Returns.

| dmy | -0.32013E-01 | 0.2925 | -0.109 | 0.91301 |
| Panel E |  |  |  |  |
| $\Delta$ working capital/total assets | -0.92307 | 0.4472 | -2.064* | 0.03900 |
| $\mathrm{R}_{1}$ | 0.76876 | 0.5892 | 1.305 | 0.19200 |
| dmy | -0.60297 | 0.5741 | -1.050 | 0.29358 |
| $\Delta$ working capital/total assets | -0.65783 | 0.6945 | -0.947 | 0.34537 |
| $\mathrm{R}_{t+1}$ | 1.3318 | 0.2893 | 4.603* | 0.00001 |
| dmy | -0.38414E-01 | 0.2945 | -0.130 | 0.89644 |

The findings suggest that the accounting descriptors' information about the direction and size changes of future earnings is impounded in this year' stock returns for small companies while the information of large companies is impounded in next year's stock returns.

Specifically, the $\% \Delta$ sales, the depreciation/fixed assets, the $\% \Delta$ sales/total assets, the $\Delta$ sales/cash, the $\Delta$ working capital/total assets and the $\% \Delta$ sales/total assets variables indicate that for small companies accounting information is impounded
in this year's stock returns.

## 1981-1985 Period

To examine whether the lagged impounding phenomenon, during the sub-period 198185, is valid for small or large companies or for both small and large companies, a multivariate regression model is run. During this period, the findings suggest that the lagged impounding phenomenon is mostly valid for large companies. The results are shown in table 7.2.

Table 7.2: Multivariate Regression Analysis For The Stores Industry Examining The Effect Of Large And Small Companies On The Information Impounded In This Year's Or Next Year's Stock Returns During Period 1981-85.

| Accounting Descriptors | Coefficient | Standard Error | $t$-statistic | problti> $=x$ |
| :---: | :---: | :---: | :---: | :---: |
| Panela |  |  |  |  |
| sales/total assets | 0.11536E-01 | 0.7433E-02 | 1.552 | 0.12065 |
| $\mathrm{R}_{1}$ | 0.14377 | 0.2019 | 0.712 | 0.47636 |
| dmy | 0.58223 | 0.2170 | 2.683* | 0.00730 |
| sales/total assets | $0.11536 \mathrm{E}-01$ | 0.7433E-02 | 1.552 | 0.12065 |
| $\mathrm{R}_{4+1}$ | 0.58223 | 0.2170 | 2.683* | 0.00730 |
| dmy | 0.14377 | 0.2019 | 0.712 | 0.47636 |
| Panel B |  |  |  |  |
| $\Delta$ working capitla/total assets | -0.48453 | 0.3052 | -1.588 | 0.11240 |
| R ${ }_{1}$ | 0.14840 | 0.2065 | 0.719 | 0.47226 |
| dmy | 0.95789 | 0.3971 | 2.412* | 0.01586 |
| $\Delta$ working capital/total assets | -0.48283 | 0.3026 | -1.595 | 0.11062 |
| $\begin{aligned} & \mathbf{R}_{1+1} \\ & \mathrm{dmy} \end{aligned}$ | 0.97081 | 0.4101 | 2.367* | 0.01791 |

For large companies the information about future earnings changes, contained by the accounting descriptors, is impounded in next year's stock returns. Especially the information contained by the sales/total assets and the $\Delta$ working capital/total assets variables is impounded in next year's stock returns.

## 1982-1986 Period

To examine whether the lagged impounding phenomenon is valid for small or large
companies or for both small and large companies, a multivariate regression model is run. During the period 1982-86, the findings suggest that the lagged impounding phenomenon is valid for large companies. The results are shown in table 7.3.

Table 7.3: Multivariate Regression Analysis For The Stores Industry Examining The Effect Of Large And Small Companies On The Information Impounded In This Year's Or Next Year's Stock Returns During The Period 1982-86.

| Accounting Descriptors | Coefficient | Standard Error | t-statistic | problas ${ }^{\text {a }}$ ( |
| :---: | :---: | :---: | :---: | :---: |
| Panela |  |  |  |  |
| $\overline{\text { debtors ratio }}$ | $0.11406 \mathrm{E}-05$ | 0.4137E-05 | 0.276 | 0.78318 |
| $\mathrm{R}_{1}$ | 0.11607 | 0.1409 | 0.824 | 0.41151 |
| dmy | 0.25889 | 0.1190 | 2.176* | 0.03123 |
| $\Delta$ debtors ratio | 0.11104E-05 | 0.1913E-05 | 0.580 | 0.56169 |
| $\mathrm{R}_{\text {t+1 }}$ | 0.27627 | 0.1012 | 2.730* | 0.00634 |
| dmy | 0.21935E-03 | 0.1370 | 0.002 | 0.99872 |
| Panel B |  |  |  |  |
| Return on opening equity | 0.49969E-02 | $0.2964 \mathrm{E}-02$ | 1.686* | 0.09415 |
| R | 0.11115 | 0.1408 | 0.790 | 0.43118 |
| dmy | 0.25269 | 0.1191 | 2.121* | 0.03572 |
| return on opening equity | 0.47162E-02 | 0.2585E-02 | 1.825* | 0.06804 |
| $\mathrm{R}_{\text {t+1 }}$ | 0.25780 | 0.1026 | 2.513* | 0.01197 |
| dmy | 0.11603E-01 | 0.1359 | 0.085 | 0.93197 |
| Panel C |  |  |  |  |
| Dworking capital/total assets | -0.74250 | 0.6393 | -1.161 | 0.24770 |
| $\mathrm{R}_{4}$ | $0.64863 \mathrm{E}-01$ | 0.1691 | 0.383 | 0.70202 |
| dmy | 0.25190 | 0.1373 | 1.834* | 0.06903 |
| $\Delta$ working capital/total assets | -0.69677 | 0.2820 | -2.471* | 0.01347 |
| $\mathrm{R}_{\text {t+1 }}$ | 0.24560 | 0.1675 | 1.466 | 0.14261 |
| dmy | 0.22580E-01 | 0.1838 | 0.123 | 0.90224 |

The $\Delta$ in debtors ratio, the return on opening equity and the $\Delta$ in working capital/total assets variables, all indicate that for large companies, the information about future earnings changes is reflected in next year's stock returns.

## CHEMICAL INDUSTRY

## 1982-1986 Period

To examine whether the lagged impounding phenomenon is valid for small or large companies or for both small and large companies, a multivariate regression model is run, for the chemical industry during the period 1982-86. The findings suggest that the lagged impounding phenomenon is valid for large companies. The results are shown in table 7.4.

Table 7.4 Multivariate Regression Analysis For The Chemical Industry Examining The Effect Of Large And Small Companies On The Information Impounded In This Year's Or Next Year's Stock Returns During The Period 1982-86.

| Accounting Descriptors | Coefficient | Standard Error | $t$-statistic | probltl> $=$ x |
| :---: | :---: | :---: | :---: | :---: |
| Panela |  |  |  |  |
| $\Delta$ times interest earned | 0.27906E-05 | 0.2230E-05 | 1.252 | 0.21072 |
| R | 0.16775 | 0.2408 | 0.697 | 0.48606 |
| dmy | 0.10894 | 0.2665 | 0.409 | 0.68269 |
| $\Delta$ times interest earned | 0.73788E-05 | $0.9624 \mathrm{E}-05$ | 0.767 | 0.44529 |
| $\mathrm{R}_{\text {t+1 }}$ | 0.23034 | 0.1106 | 2.082* | 0.04021 |
| dmy | 0.23757 | 0.1507 | 1.577 | 0.11848 |
| Panel B |  |  |  |  |
| \% $\Delta$ times interest earned | 0.52426E-05 | 0.4202E-05 | 1.247 | 0.21222 |
| R | 0.16774 | 0.2408 | 0.697 | 0.48608 |
| dmy | 0.10894 | 0.2665 | 0.409 | 0.68270 |
| \% $\Delta$ times interest earned | 0.13895E-04 | $0.1813 \mathrm{E}-04$ | 0.766 | 0.44555 |
| $\mathrm{R}_{\text {+1 }}$ | 0.23035 | 0.1106 | 2.082* | 0.04021 |
| dmy | 0.23755 | 0.1507 | 1.576 | 0.11851 |

The $\Delta$ interest earned variable and the $\% \Delta$ interest earned variable suggest that the information of financial statement report numbers' information for large firms is impounded in next year's stock returns.

## 1983-1987 Period

To examine whether the lagged impounding phenomenon is valid for small or large companies and for both small and large companies, a multivariate regression model
is run for the period 1983-87. The findings suggest that the lagged impounding phenomenon is valid for large companies. The results are shown in table 7.5.

Table 7.5: $\quad$ Multivariate Regression Analysis For The Chemical Industry Examining The Effect Of Large And Small Companies On The Information Impounded In This Year's Or In Next Year's Stock Returns During The Period 1983-87.

| Accounting Descriptors | Coefficient | Standard Error | t-statistic | probltl $\mathbf{>}=\boldsymbol{x}$ |
| :--- | :--- | :--- | :--- | :--- |
| PanelA |  |  |  |  |
| \% $\Delta$ operating profitsales | $0.10169 \mathrm{E}-01$ | $0.6066 \mathrm{E}-02$ | $1.677^{*}$ | 0.09364 |
| $\mathrm{R}_{1}$ | 0.12167 | 0.1706 | 0.713 | 0.47571 |
| dmy | $-0.17473 \mathrm{E}-01$ | 0.1865 | -0.094 | 0.92536 |
|  |  |  |  |  |
| \% $\Delta$ operating profit/sales | $0.98145 \mathrm{E}-02$ | $0.1919 \mathrm{E}-01$ | 0.511 | 0.61022 |
| $\mathrm{R}_{1+1}$ | 0.19135 | $0.8029 \mathrm{E}-01$ | $2.383^{*}$ | 0.01907 |
| dmy | $0.22217 \mathrm{E}-01$ | 0.1231 | 0.180 | 0.85713 |

The $\% \Delta$ operating profit variable reveals that during the period 1983-87, the financial statement report numbers' information concerning the direction and sign of future earnings changes for large companies is impounded in next year's stock returns.

### 7.4 CONCLUDING REMARKS

This chapter investigates whether the lagged impounding phenomenon is valid for all classes of companies. Specifically, an investigation is carried out whether the lagged impounding phenomenon is valid only for large or small companies.

## Stores Industry

The findings suggest that the annual financial statements report numbers' information concerning the direction and size changes of future earnings changes, for large firms, is impounded in next year's stock returns while the information of the annual financial statements report numbers of small firms, is impounded in this year's stock returns. My findings are in accordance with Greig (1992) ${ }^{1}$.

A possible explanation of why large companies' information concerning future earnings sign and size changes is impounded in next year's stock returns might be that it takes a longer time for analysts and investors to analyse the implications of current earnings for future earnings. The rationale might be that large companies financial statements are quite complex while the financial statement of small companies are simpler and easier to be interpreted.

During the period 1980-84, the accounting descriptors whose information about future earnings changes are reflected in next year's stock returns are the following:

- \% $\Delta$ sales;
- $\Delta$ depreciation/fixed assets;
- $\Delta$ sales/total assets;
- $\Delta$ sales/cash;
- $\Delta$ working capital/total assets;

It is worth noticing that the above accounting descriptors capture similar operating

[^27]characteristics. For example, the sales appear in more than one descriptor.
During the period 1981-85, the accounting descriptors whose information about future earnings changes is reflected in next year's stock returns are the following:

- sales/total assets;
- $\Delta$ working capital/total assets;

During the period 1982-86, the accounting descriptors whose information is reflected in next year's stock returns are the following:

- $\Delta$ debtors ratio;
- return on opening equity;
- $\Delta$ working capital/total assets;

The $\Delta$ working capital/total assets variable exhibits information concerning the direction and size of future earnings throughout the periods 1980-84, 1981-85 and 1982-86. However, the estimates within each estimation period are not from independent observations.

## Chemical Industry

The findings for chemical industry suggest that the annual financial statements report numbers' information concerning the direction and size changes of future earnings changes, for large firms, is impounded in next year's stock returns while the information of the annual financial statements report numbers' information, for small firms, is impounded in this year's stock returns. The findings are, once more, in accordance with Greig's (1992) argument that accounting ratios of small firms are systematically different from those of large firms.

During the period 1982-86, three accounting descriptors' information about future earnings changes is reflected in next year's stock returns. These accounting descriptors are the following:

- the $\Delta$ times interest earned; and
- the $\% \Delta$ times interest earned.

During the period 1983-87, the only accounting variable exhibiting lagged impounding
phenomenon is

- the $\% \Delta$ operating profit/sales variable.

A possible explanation of why large companies' information concerning future earnings sign and size changes is impounded in next year's stock returns might be that it takes a longer time for analysts and investors to analyse the implications of current earnings for future earnings. The rationale might be that large companies financial statements are quite complex while the financial statement of small companies are simpler and easier to be interpreted.

## CHAPTER EIGHT

## Conclusions and Future Research

### 8.1 INTRODUCTION

The thesis provides empirical evidence on the predictive ability and information content of UK financial statement report numbers. Specifically, it is examined whether the Ou and Penman (1989a) finding for the US that financial statement numbers convey information about the sign of the one year ahead earnings change, and that this is not reflected in current stock returns. The OP give little or no explanation for their findings: there is no economic rationale given to explain why some financial statement number predict eanrings changes. Indeed, OP purposely avoid such a discussion since they wish to replicate the position of a naive investor.

However, the main focus of this thesis is whether the lagged impounding results of OP transfer to UK, and if so, whether they are driven by cross sectional differences; whether they are driven by companies' size and last, whether they are driven by the negative and/or positive values of earnings changes.

Two different industry groupings, stores and chemicals, both separately and combined are investigated. In the first stage, the ability of 83 accounting descriptors to predict earnings one year ahead, over the periods 1980-1988, 1980-1984, 19811985, 1982-1986, 1983-1987 aned 1984-1988. Although, the results are mixed, they seem to give support to Greig's postion, that differences between industries are associated with predictive ability.

In the second stage, it is examined whether the information contained in accounting descriptors about future earnings is impounded in contemporaneous returns. The results suggest that lagged impounding is far more frequent when the industries are aggregated, than when examined separately. Moreover, the results suggest that the impounding process tends to be focussed within individual industry sectors.

In the third stage, it is examined whether the predictive informaiton of financial statement numbers for future earnings changes is only valid for the negative and/or positive distribution of the earnings changes. The evidence is however, mixed.

In the last stage, it is examined whether the lagged impounding phenomenon of the financial statements report numbers' predictive information for future earnings changes is confined to large or small companies. The evidence suggests that the
lagged impounding phenomenon is confined to large companies.
The section 8.2 reports the main findings of each chapter. Section 8.3 explores discusses explanations offered by other research papers about the relationship between financial statement ratios and future earnings changes; section 8.4 explains the policy implications of the thesis findings and section 8.5 suggests future research direction.

### 8.2 CONCLUSIONS

Chapter one reviews the different swings in mood in capital markets research beginning with the Ball and Brown (1968) and ending with Ou and Penman (1989). In late 1960's and early 1970's, the belief that the market is efficient is very strong and we experience a number of event studies investigating what information accounting pertains. However, by the mid 1980's, academics realise how little we know about market efficiency and the appearance of market anomalies - E/P ratio, size effect, the crash of 1987, volatility -and perhaps the most challenging evidence against efficiency, the underutilisation of financial statements, shake the faith in market efficiency. The question becomes then, whether the market is efficient or not. But, entering the late 1980's and early 1990's, the question posed is no longer whether the market is efficient, but how the market processes information (i.e impounding of information in current prices or not impounding). A turn to the traditional issues is witnessed, with emphasis on the relation between earnings and prices and the information content of earnings and non-earnings data.

It is high time, the question was addressed of how financial statement numbers can be used in investment worth. An understanding of how one can use the financial statement information in assessing how much a firm is worth would clearly be an important contribution. The Ou and Penman (1989) controversy represents an understanding of valuation. This would have been true even without the result on the ability to predict future stock returns. Although crude, it focus our thinking of how accounting information can be used by investors.

Chapter two explores the background to the research and defines the accounting
descriptors used in the empirical tests. It draws attention on the problems faced when dealing with ratio analysis as well as on future replications, of using the same accounting descriptors of this thesis. A different definition of one accounting descriptor used, might alter the empirical results.

Chapter three takes an earnings change prediction approach to investigate whether U.K stores and chemical industries annual financial statement numbers contain information concerning the direction and size of one-year ahead earnings changes. It provides empirical evidence for a predictive information link between these financial statement numbers and future earnings changes.

In Stores Industry, the findings (via logit) suggest that some financial accounting variables exhibit information concerning the direction of next year's earnings changes. However, the ability of some of these accounting variables to describe future earnings changes disappears once outliers [these may be extraordinary items] are deleted from the sample.

The accounting descriptors which are robust to all the logit tests carried out [with and without outliers] are the following:

- the \% $\Delta$ current ratio;
- the inventory;
- the times interest earned; and
- the return on total assets.

The findings (via regression) suggest that the accounting descriptors can predict the size of the $\% \Delta$ operating profit as well as the sign. However, different accounting variables from the ones reported in the logit models are found to capture information concerning the size and sign of the $\% \Delta$ operating profit one-year ahead.

It is noteworthy that the accounting variable

- $\Delta$ inventory/turnover,
found to exhibit information about future earnings changes sign and size, is also reported by OP (1989a) as one of six descriptors to describe the sign of the future earnings changes for the periods 1965-72 and 1973-77.

In Chemical Industry, the findings (via logit) suggest that some financial accounting variables exhibit information concerning the direction of next year's
earnings change. However, the ability of some of these accounting variables to describe future earnings changes disappears once outliers [these may be extraordinary items] are deleted from the sample.

The accounting variables which are robust to all the logit tests carried out [with and without outliers] and predict next year's earnings changes are the following:

- the sales/total assets;
- the \% $\Delta$ total assets;
- the debtors ratio; and
- the sales/total assets.

The findings (via regression) suggest that the accounting descriptors can predict the size of the $\% \Delta$ operating profit as well as the sign. The two accounting variables which exhibit information about the size and sign of the $\% \Delta$ operating profit one-year ahead are the following:

- the sales/total assets; and
- the $\% \Delta$ total assets.

Ohlson (1991) recommends the aggregated total assets as the accounting descriptor which can shed light on the valuation concept ${ }^{1}$.

In Stores and Chemical Industries Together, the findings (via logit) suggest that, when industries are aggregated, some financial accounting variables exhibit information concerning the direction of next year's earnings change. However, the ability of all these accounting variables to describe future earnings changes one-year ahead disappears once outliers [these may be extraordinary items] are deleted from the sample.

The findings (via regression) suggest that the accounting descriptors can predict the size of the $\% \Delta$ operating profit as well as the sign. The accounting variables which exhibit information about the size and sign of the $\% \Delta$ operating profit one-year ahead are the following:

- the $\Delta$ inventory/total assets;
- the \% $\Delta$ sales;

[^28]- the $\Delta$ depreciation/fixed assets;
- the return on opening equity;
- the $\% \Delta$ return on opening equity;
- the times interest earned and
- the return on closing equity.

None of the above accounting descriptors are reported to capture information about the sign and size of the future earnings when the stores and chemical industries are examined separately. No accounting descriptor appears to contain information about future earnings changes under the two univariate logit models [first model with outliers and second model without outliers]. Moreover none of the accounting descriptor is the same as the ones presented by OP [Ou and Penman (1989), p. 307]. Overall the findings suggest that the power of the tests to predict the sign (via logit) and size (via regression) when the industries are aggregated is poor. Only in the case of the times interest earned variable, evidence suggests that this accounting descriptor predicts the sign (via logit) of future earnings changes for the stores industry and when the stores and chemical industries are aggregated, the same descriptor is found to predict the size (via regression) of future earnings changes. However, overall the evidence suggests that when industries are tested separately, the findings reveal that different accounting descriptors describe future earnings sign and size changes in different industries. This is in accordance to Greig (1992) argument that "the summary measure "Pr" of the OP analysis is a function of accounting ratios. Ratios vary systematically across firms as a function of future earnings changes and also vary systematically cross-sectionally as a function of risk, size and determinants of expected returns [ Greig (1992), p. 415]. In other words, economic factors cause the link between financial statement numbers and future earnings changes.

But the question asked now is whether the overall results are a consequence of a systematic relationship between these industry accounting descriptors and future earnings changes and whether expert analysts and investors can detect this relationship. The answer might lie on whether these accounting descriptors capture the "temporary" or " permanent" changes in current earnings. The permanent component will persist over time while the transitory will be only time-specific.

Thus the consistency of the accounting descriptors' coefficient signs and size across time and across industry is tested in chapter 4.

Chapter four takes an earnings change prediction approach to investigate the incremental information content of financial statement report numbers over current earnings, over shorter periods than in the previous chapter. I examine the periods 1980-84, 1981-85, 1982-86, 1983-87 and 1984-88. It provides empirical evidence for an unsystematic relationship between these financial statement report numbers and future earnings changes over the periods examined.

In Stores Industry, the findings (via logit) suggest that a firm's financial statement report numbers predict the direction of one-year ahead earnings changes over the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88. The accounting descriptors which predict future earnings changes over all the periods examined are

- the $\% \Delta$ current ratio and
- the times interest earned variable.

However, the predictive information link between these two financial descriptors and future earnings changes disappears when the outliers are deleted from the sample.

The findings (via regression) suggest that a firm's financial statement report numbers predict the size as well as the sign of the $\% \Delta$ operating profit variable. However, this predictive ability of the accounting descriptors is not systematic. It is time-specific.
In Chemical Industry, the findings (via logit) suggest that a firm's financial statement report numbers predict the direction of one-year ahead earnings changes over the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88. The accounting descriptors which predict future earnings changes over all the periods examined are

- the debtors ratio;
- the return on opening equity and
- the return on total assets.

However, the predictive information link between these two financial descriptors and future earnings changes disappears when the outliers are deleted from the sample.

The findings (via regression) suggest that a firm's financial statement report
numbers predict the size as well as the sign of the $\% \Delta$ operating profit variable. However, this predictive ability of the accounting descriptors is not systematic. It is time-specific.

In Stores and Chemical Industries Together, the findings (via logit) suggest that a firm's financial statement report numbers do not predict the direction of oneyear ahead earnings changes over the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88.

The findings (via regression) suggest that a firm's financial statement report numbers predict the size as well as the sign of the $\% \Delta$ operating profit variable. However, this predictive ability of the accounting descriptors is not systematic. It is time-specific.

Overall the findings (via logit) suggest that a firm's financial statement report numbers predict the direction of one-year ahead earnings changes over the periods 1980-84, 1981-85, 1982-86, 1983-87, 1984-88 and 1980-88. However, there is not a time-consistent relationship between the financial statement report numbers and future earnings changes. The predictive ability of the financial statement report numbers regarding future earnings changes is time-specific. The findings are in accordance with Woodmore (1991) ${ }^{2}$ and Holthausen and Larcker (1992) ${ }^{3}$.

The accounting descriptors, under the LOGIT methodology, are found to predict the sign of the $\% \Delta$ operating profit more systematically than under the REGRESSION methodology. In addition, under the regression analysis, the accounting descriptors do not seem so systematic in predicting the size of the $\% \Delta$ operating profit.

The accounting variables exhibiting incremental information content over current earnings in stores industry differ from those exhibiting incremental information content over current earnings in chemical industry. The findings suggest that the difference in the accounting ratios reflects an industry differential. Also, the findings

[^29]suggest poor power of the tests when the stores and chemical industries are aggregated. Ou and Penman (1989, p. 299) state that "if a general model is not a good representation for all firms ( to the extent to which different characteristics generate future earnings in different firms in different ways , we again introduce a conservative bias to the tests". This conservative bias is also emphasized in their conclusion (pp. 327-328) that "one suspects that industry-specific or firm-specific models would produce improvements".

Overall the findings are in accordance with Greig (1992) who argues that the economic factors are the cause of the information link between the financial statement numbers and future earnings changes.

Chapter five examines whether the financial statement numbers' information, concerning the direction and size changes of future earnings, is impounded in the current year's stock return or in the following year's stock return. Specifically an investigation is carried out to examine whether the U.K stock market exhibits lagged impounding characteristics, similar to the ones reported for the U.S.A market by Ou and Penman (1989a).

The findings suggest that the information concerning future earnings changes contained by the financial statement numbers, is impounded in the current year's stock return, in the majority of cases. Thus the maintained hypothesis of market efficiency is supported by the majority of the findings.

However, there is a number of accounting descriptors, whose information concerning future earnings changes, is impounded in the following year's stock return and not in the current. These findings support the OP hypothesis that there is indeed a lagged impounding phenomenon in the market. This lagged impounding phenomenon is not consistent over all the periods examined.

The findings also reveal that there is a number of accounting descriptors whose information is neither reflected in the current year's stock return nor in the following year's stock return. These cases are referred to as "other effects". These "other effects" are not tested empirically in this thesis. Only theoretical explanations as offered by a number of studies [Stober (1992) and Ball (1992)], have been provided. The rationale being that the main objective of the analysis carried out in this chapter, is to establish
whether there is a lagged impounding phenomenon; that is, a time lag of one year, in the market, before all accounting information is impounded in current prices.

Chapter six examines whether the lagged impounding phenomenon of financial statement report numbers is valid for both negative and positive values of the $\% \Delta$ operating profit variable changes. It provides empirical evidence of a valuation link between financial statement numbers' information and stock returns for the stores and chemical industries.

The findings suggest that for the stores industry, during the period 1980-84, only in the case of the $\% \Delta$ sales variable, there exists clear evidence that the ability of the $\% \Delta$ sales variable to predict future earnings' sign and size changes is valid only for the negative values of the $\% \Delta$ operating profit variable. Also, the findings reveal that the $\% \Delta$ sales/inventory variable exhibits a lagged impounding phenomenon as reported by Ou and Penman (1989a). This lagged impounding phenomenon is valid only for the positive values of the $\% \Delta$ operating profit variable.

The rest of the evidence presented for the stores industry during the periods 1980-84, 1981-85 and 1982-86 is spurious. The reason for this is that the accounting descriptors exhibit information concerning the sign and size of earnings changes only when regressed with the current year's stock return and the following year's stock return.

For the chemical industry, the findings present spurious evidence as well. The accounting descriptors exhibit information concerning the sign and size of earnings changes only when regressed with the current year's stock returns and the following year's stock returns.

Possible explanations for the results might lie in the activities of analysts. For example, analysts engaged in forecasting might be subjected to psychological forces [Kahneman and Tversky (1975)], or to the "herding" behaviour [Truemann (1994)] or to other personal incentives, like for example, analysts release forecasts similar to those previously announced by other analysts, even when this is not justified by their information. A second explanation of why the information is not reflected in the current stock returns might be the transaction costs (Bushan 1994). The transaction costs are inversely related to firm size.

Chapter seven investigates whether the lagged impounding phenomenon is valid for all classes of companies. Specifically, an investigation is carried out whether the lagged impounding phenomenon is valid only for large or small companies.
In Stores Industry, the findings suggest that the annual financial statements report numbers' information concerning the direction and size changes of future earnings changes, for large firms, is impounded in next year's stock returns while the information of the annual financial statements report numbers' information, for small firms, is impounded in this year's stock returns. My findings are somewhat in accordance with Greig (1992) ${ }^{4}$.

A possible explanation of why large companies' information concerning future earnings sign and size changes is impounded in next year's stock returns might be that it takes a longer time for analysts and investors to analyse the implications of current earnings for future earnings. The rationale might be that large companies financial statements are quite complex while the financial statement of small companies are simpler and easier to be interpreted.

During the period 1980-84, the accounting descriptors whose information about future earnings changes are reflected in next year's stock returns are the following:

- the $\% \Delta$ sales;
- the $\Delta$ depreciation/fixed assets;
- the $\Delta$ sales/total assets;
- the $\Delta$ sales/cash;
- the $\Delta$ working capital/total assets;

It is worth noticing that the above accounting descriptors capture similar operating characteristics. For example, the sales appear in more than one descriptor.
During the period 1981-85, the following accounting descriptors' information about future earnings changes is reflected in next year's stock returns:

- the sales/total assets;
- the $\Delta$ working capital/total assets;

[^30]During the period 1982-86, the following accounting descriptors' information about future earnings changes is reflected in next year's stock returns:

- the $\Delta$ debtors ratio;
- the return on opening equity;
- the $\Delta$ working capital/total assets;

The accounting variable $\Delta$ working capital/total assets exhibits information concerning the direction and size of future earnings throughout the periods 1980-84, 1981-85 and 1982-86. This information is impounded in next year's stock returns. However, this lagged impounding phenomenon exhibited by the $\Delta$ working capital/total assets. However, the estimates within each estimation period are not from independent observations however.

In Chemical Industry, the findings suggest that the annual financial statements report numbers' information concerning the direction and size changes of future earnings changes, for large firms, is impounded in next year's stock returns while the information of the annual financial statements report numbers' information, for small firms, is impounded in this year's stock returns. My findings are somewhat in accordance with Greig's (1992) argument that accounting ratios of small firms are systematically different from those of large firms.

During the period 1982-86, the accounting descriptors whose information about future earnings changes are reflected in next year's stock returns are the following:

- the $\Delta$ times interest earned; and
- the \% $\Delta$ times interest earned.

During the period 1983-87, the only accounting variable exhibiting lagged impounding phenomenon is the $\% \Delta$ operating profit/sales.

Overall the findings suggest that there is a large size effect. A possible explanation of why large companies' information concerning future earnings sign and size changes is not impounded in the current year's stock returns, but is impounded in the following period, might be that it takes a longer time for analysts and investors to analyse the implications of current earnings for future earnings. The rationale might be that large companies financial statements are quite complex while the financial statement of small companies are simpler and easier to be interpreted.

### 8.3 POLICY IMPLICATIONS

The findings in chapters 3,4 and 5 are interpreted as evidence that even when signals about future earnings are imbedded in the balance sheet, footnotes and elsewhere, the market fails to impound it completely until those signals translate into an impact on current earnings. This shows that financial statement analysis works and that there is some point to fundamental analysis even when it is based solely on readily available accounting disclosures. The FRS3 "Reporting Financial Performance" may be interpreted as a response to the findings. The new Statement of Total Recognised Gains and Losses makes the cost of reading and understanding the position of the company much lower.

The findings in chapter 7 are interpreted as evidence that accounting ratios of small firms are systematically different from those of large firms. Financial statement numbers' information concerning the sign and size of future earnings changes is impounded with one year' lag in stock returns, for large companies. This shows that large companies' annual report accounts are more complex than the accounts of small firms and the market needs more time to investigate the implications of current earnings for future earnings.

Some groundwork on the time-series and cross-sectional relations among accounting numbers has been carried out. Two industries, the stores and chemicals are first tested separately and then together. The findings suggest that the power of the tests when the two industries are aggregated, is poor. The rationale is that accounting ratios vary systematically both across firms and across time for reasons other than their association with future accounting earnings changes.

### 8.4 LIMITATIONS OF THE THESIS AND FUTURE RESEARCH

- The research covered by the thesis should be further extended by examining whether the financial statements' predictive ability can be justified by economic rationale. During the period examined, 1980-88, the U.K. market experienced considerable swings in trends. For example, the change in monetary policy with the newly Thatcher elected government, the house boom in 1983, the high interest rates [as high as 15 per cent] in 1986, the stock market crash in 1987.
- The thesis' results might be sensitive to the definitions of the accounting descriptors employed. Greig (1992), despite using the same definitions of the accounting descriptors adopted by Ou and Penman (1989a), finds different results from those documented by Ou and Penman. He attributes the difference in the results to a slight different definition of an accounting descriptor. Future research might therefore examine the sensitivity of the results to different definition of accounting descriptors.
- Moreover, the predictive information link between financial statement numbers might be a statistical flaw. Unfortunately, there is no one test that is accepted as the standard test for heteroscedasticity. The logit and regression models employed in this thesis are corrected for heteroscedasticity using the White-adjustment. No effort was made to find altenative GLS specifications of the model and therefore, the use of a different test might result in different empirical evidence.
- Variations in one year ahead changes in earnings are explained by (i) variations in a descriptor and (ii) variations in contemporaneous returns. This approach is intended to capture the informaiton contained in a descriptor which is not already reflected in returns. However, this partitioning takes place within the OLS procedures and may not fully reflect the preferences of investors; for example, the mapping between industry characteristics and expected returns may not be linear.
- The thesis can be further extended by focusing on what financial analysts actually do and why they do not trace the lagged impounding phenomenon even when it is time-specific. The general analysts decision context can be first investigated and second the incentives faced by analysts. Questionnaires might be sent to financial analysts to examine how they actually make their forecasts; how they analyse large
firms. The findings can be analyzed using the informational efficiency framework [Grossman and Stiglitz (1976, 1980)]. Under this perspective, trading and investment by professionals help bring prices in line with fundamentals and a firm can be misprised because transaction costs and processing costs analysis can prevent professionals from trading in its shares. Thus, the combination of investor heterogeneity (in terms of costs faced by analysing information) and transaction costs can result in lagged impounding existing up to the magnitude of transaction costs. Firms with high transaction costs can display significant misprising or lagged impounding while those with low transactions costs are unlikely to be misprised. Firms with low transaction costs are unlikely to display lagged impounding even when analysts following these firms may not fully appreciate the time-series properties of earnings and issue inefficient forecasts [ Bhushan (1994)].

# Binary Specification is formed based on the mean of the \% $\Delta$ operating profit 

## Stores Industry

Table A1: Univariate Logit Estimation For The Stores Industry For The Identification Of The Accounting Descriptors Exhibiting Information About Future Earnings Changes Throughout The Period 1980-1988.

| Accounting Descriptors | Accounting Coefficient | Standard Error | $t$-statistic | $\begin{aligned} & \text { prob\|t\|> } \\ & =\mathrm{x} \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: |

[^0]:    ${ }^{1}$ They study forecast errors because the forecast error is a transformation of past and current earnings per share; the reason being that it constitutes a signal from an information system.

    May (1971) using a combination of Beaver's and Ball and Brown's technique, confirmed the association between quarterly earnings announcements and stock price changes. Martin [1971] constructed a model based on accounting variables to explain variability in earnings-price ratios. He found that accounting information is useful for investment decision making.

    Ball-Brown (1968) did not normalize their measures of unexpected earnings with initial security price. This normalisation procedure has become common during recent years. Christie (1987) supports this procedure.

    The purpose of the empirical analysis is to assess whether the distribution of security returns conditional upon the signal realization (forecast error) differs from the unconditional (or marginal) contribution. "The reason a dependency exists is rested upon the premise that prices and earnings both are the result of mapping from a common underlying set of events [Gonedes (1975)]

[^1]:    ${ }^{5}$ BLM (1980) view observed carnings ( y ) as a mixture of ungarbled earnings ( $\mathrm{X}_{1}$ ) and earnings with no pricing implication $\left(\varepsilon_{\mathrm{E}}\right)$. They make the valuation assumption for each security (where price is a multiple of ungarbled earnings) and derive the relationship that the percentage change in price equals the percentage change in expected ungarbled earnings. More formally, BLM assume that yt follows a first order moving average coefficient and $\mathrm{E}(\mathrm{at})=0$. They derive the empirical relation between price and observed earnings as follows:

    $$
    \Delta \frac{r_{t}}{P_{t-1}}=\frac{\Delta \Sigma\left(\Lambda_{t+k}\right)}{E\left(X_{t+k-} X_{t-1}\right)}=(1-\theta) \Delta Y_{t}+(1-\theta) \theta a_{t-1}-e_{t-1}
    $$

    $\mathrm{E}\left(\mathrm{x}_{1+\mathrm{k}}\right)$ can be thought as permanent earnings and $\Theta \mathrm{a}_{1}+\varepsilon_{1}$ as the transitory component of observed earnings. A simplified case occurs when $a_{1-1}, \varepsilon_{1}$ and $\varepsilon_{1-1}$ equals zero. Then the percentage change in price becomes directly proportional to the percentage change in earnings, where $(1-\Theta)$ is the proportionality factor.

    The BLM model is limited because of the absence of a useful distinction of xt (ungarbled earnings) and dt (dividends). Ungarbled earnings cannot embody the relevant attributes for determining value unless one defines ungarbled earnings as a function of an observable variable, independent of value (price). Dividends, on the other hand, are observable variables whose relevance is derived from non-arbitrage conditions. Ohlson dividend capitalization model is expressed as:

    $$
    P_{t}=(1+R)^{-1} E\left(\dot{P}_{t+1}+\dot{d}_{t+1-} n_{t}\right)
    $$

    where $R$ equals the security's expected rate of return and nt is the information set at time $t$. Combining with BLM specifications, Ohlson relates ungarbled earnings to expected dividends through a constant $\gamma$, which represents the payout coefficient associated with expected ungarbled earnings, that is, expected dividends are the expected ungarbled earnings scaled by the constant $\gamma$.[Cho and Jung(1991) p. 90]

    They explore the information content of prices with respect to firm size and its relation to the predictive accuracy of price-based earnings forecasts.

[^2]:    ${ }^{8}$ The underlying assumption of a constant response coefficient in cross-sectional studies, i.e investors react identically to earnings of all firms, is obviously unrealistic. This assumption might be more tenable for time-series returns/earnings regressions, since investors reaction to earnings of the same firm over time might be more stable than across different firms. The earnings response coefficient (ERC) is defined as the effect of a dollar of unexpected earnings on stock returns and typically measured as a slope coefficient in the regression of abnormal stock returns on the appropriately scaled unexpected earnings.

    CAPM expresses mean returns in terms of expected returns on the market portfolio, the return on risk-free asset and the firm's beta. The empirical representation of CAPM is the market model.

[^3]:    ${ }^{10}$ This is implied from the CAPM (capital asset pricing model) where the firm's expected rate of return is a function of the firm's systematic risk (beta) and risk-free interest rate.

[^4]:    ${ }^{11}$ This is known as the "naive investor" or "functional fixation" hypothesis.

[^5]:    ${ }^{12}$ Good and Meyer(1973) find that high and low P/E ratios diminish when earnings are adjusted for differences in accounting methods used for depreciation and extraordinary items. Eskew(1975) report that investors in oil and gas stocks adjust for differences between the "full-cost" and "successful-efforts" methods in accounting.

[^6]:    ${ }^{13}$ Professor J. V. Horne argues that "the crash makes us realize that prices are not entirely efficient. I think by and large all of us in finance are somewhat more humble".

[^7]:    ${ }^{1}$ The price of securities in terms of expected payoffs is well established of course, but how price is determined in terms of the existing information that conditions those expectations is not well established. This is fundamental or financial statement analysis.

[^8]:    ${ }_{3}^{2}$ However, Ou and Penman (1989a) use individual ratios and not what Ohlson's theory supports, the total assets.
    ${ }^{3}$ Observed dividends are uninformative so that observing relationships between dividends and (accounting) information will not indicate value relevance.
    ${ }^{4}$ The calculation of earnings does not involve dividends. Dividends are at the discretion of management but earnings are not. Closing book values are not affected by current dividends but it is from the post-closing book values that subsequent dividends are paid. Thus the link to future dividends is explicit in accounting. The breakthrough is that it drives us out of the dividend conundrum.

[^9]:    ${ }^{5}$ In 1961, in the context of the debate concerning whether the value of the firm is related to earnings, dividends or both, Modigliani and Miller show how to value a company consisting entirely of equity shares. They conclude that the value of the company is not related to dividends. They define the value of the company as $\mathrm{Vt}=\mathrm{Dt}+\mathrm{Vt}+\mathbf{1 - ( \mathrm { It } - ( \mathrm { Xt } - \mathrm { Dt } ) ) / 1 + \mathrm { r }}$
    $\mathrm{Vt}=\mathrm{Vt}+1+(\mathrm{Xt}-\mathrm{It}) /(1+\mathrm{r})$
    The MM61 paper was not designed with accounting theory in mind. Therefore, it does not deal with the general setting of the informational needs of investors. For some time the notion of economic income, as the measure which accounting measures should try to reflect, has been proposed by accountants.

[^10]:    ${ }^{6}$ Holthausen and Larcker(1989) model might be more susceptible to simply detecting misspecification in the excess return measures.

[^11]:    ${ }^{7}$ - $\Delta=$ absolute change;
    ${ }_{9}^{8} \% \quad \Delta=$ percentage change.
    This superiority of $\operatorname{Pr}$ over $E_{t-1}$ is inferred because (i) Ou and Penman find that $\operatorname{Pr}$ outperforms $\mathrm{P}_{\mathrm{t}}$ in predicting and (ii) we know (from Beaver, Lambert, Ryan) that $P_{t-1}$ has more information about $E_{q}$ than $E_{7-1}$.

[^12]:    ${ }^{10} \mathrm{Ou}$ and Penman (1989b) attempt to relate their work to well-known anomalies, like the Earnings/price anomaly in their subsequent paper. However, the paper is quite complicated and difficult to understand.

[^13]:    ${ }^{11}$ Datastream is an extensive on-line system of databases covering, inter alia, domestic (United Kingdom) and international company accounts.

[^14]:    ${ }^{12}-\Delta=$ absolute change of the accounting descriptor;
    $\% \quad \Delta=$ percentage change of the accounting descriptor;

[^15]:    ${ }^{1}$ Much prior research had identified nonearning items that are marginally useful in explaining contemporaneous stock returns. Examples include Lipe(1986) on components of earnings, Gonedes(1974) on several financial ratios and others.
    ${ }^{2} \mathrm{Pr}_{\mathrm{u}}$ is a measure for the assessment of the relative ability of firms to generate earnings in the subsequent year. It is so called in Ou and Penman(1989a).

[^16]:    ${ }^{3}$ The Logit procedure of LIMDEP is used.
    ${ }^{4}$ Holthausen and Larcker(1992) argue that OP way of estimating multivariate logit models might have eliminated financial statement items providing significant marginal explanatory power.

[^17]:    ${ }^{5}$ An observation is an outlier if the value in the operating profit > 10 and $<-10$. An outlier can be defined as a sudden change in the economic conditions.
    ${ }^{6} \mathrm{Ou}$ and Penman denote the change in earnings for year $t+1 \Delta \mathrm{X}_{k+1}=\mathrm{EPS}_{k+1}-$ EPS $_{u k}$-drift $\mathrm{t}_{\mathrm{k}+1}$. This is because earnings increases tend to exceed earnings decreases, in inflationary conditions.
    ${ }^{7}$ Partitioning by the mean does not have equal number of 0,1 . Partitioning by the median, equal number of 0,1 is achieved However, I did not partition by the median because the LIMDEP package used in the analysis does not provide the median.

[^18]:    ${ }^{8}$ An observation which appears to be inconsistent with the remainder of the set of data.

[^19]:    ${ }^{9}$ In this section, only the variables whose coefficient estimates differ from the ones already reported for the stores industry, are explained.

[^20]:    ${ }^{10}$ The predictive information link between financial statement numbers and stock returns.

[^21]:    ${ }^{1}$ Woodmore (1991) study is based on data from the Australian Graduate School of Management's Centre For Research in Finance database for the period 1972-1985. He could not develop a stable model either to predict abnormal returns directly as in Holthausen and Larcker (1992) or indirectly as in OP (1989a). He suggested that the OP results are time-specific.

[^22]:    ${ }^{2}$ Holthausen and Larcker (1992) attempted to predict abnormal returns directly but found that the $\mathrm{OP}{ }^{\mathrm{Mr}} \mathrm{Pr}^{\prime}$ measure did not work in the 1973-83 period.

[^23]:    1 Notice that in both the market efficiency and the lagged impounding, it is not required that the descriptor should, by itself, be significant in explaining returns. This is because $I$ am concerned with the marginal contribution of the descriptor to the information already impounded in returns. In this sense, this is a more powerful test for lagged impounding than OP, who required each descriptor to be significant by itself and also with other (pairwise) significant descriptors. OP fully recognised this, but wanted to take a conservative approach in developing their investment strategy.

[^24]:    (1992), Ball (1992)] are offered for these "other effects".
    $a_{0}$ is the constant of the accounting coefficients;
    $\mathrm{X}_{\mathrm{it}}$ is the coefficient of the accounting descriptor;
    $R_{t}$ is this year's stock returns;
    $R_{t+1}$ is the next year's stock retums.

[^25]:    a these are reterred as "other effects" in the analysis. Theoretical explanations as provided by a number or studies [Stober (1992),
    Ball (1992)] are offered for these "other effects".
    $a_{0}$ is the constant of the accounting coefficients;
    $X_{n}$ is the coefficient of the accounting descriptor;
    $R_{t}$ is this year's stock returns; $R_{t+1}$ is next year's stock returns;

[^26]:    ${ }^{1}$ These sub-periods for the stores industry have been chosen based on the evidence presented in chapter 5
    ${ }^{2}$ These sub-periods for chemical industry have been chosen based on the evidence presented in chapter 5.

[^27]:    ${ }^{1}$ Greig (1992) argues that accounting ratios are likely to vary systematically both across firms and across time for reasons other than their association with future accounting earning changes. The accounting ratios of small firms are systematically different from those of large firms, giving rise to the possibility that the $\operatorname{Pr}$ measure reported by OP to also vary systematically as a function of firm size.

[^28]:    ${ }^{1}$ The predictive information link between financial statement numbers and stock returns.

[^29]:    2 Woodmore (1991) study is based on data from the Australian Graduate School of Management's Centre For Research in Finance database for the period 1972-1985. He could not develop a stable model either to predict abnormal returns directly as in Holthausen and Larcker (1992) or indirectly as in OP (1989a). He suggested that the OP results are time-specific.
    ${ }^{3}$ Holthausen and Larcker (1992) attempted to predict abnormal returns directly but found that the OP " $\mathrm{Pr}^{\prime \prime}$ measure did not work in the 1973-83 period.

[^30]:    ${ }^{4}$ Greig (1992) argues that accounting ratios are likely to vary systematically both across firms and across time for reasons other than their association with future accounting earning changes. The accounting ratios of small firms are systematically different from those of large firms, giving rise to the possibility that the $\operatorname{Pr}$ measure reported by OP to also vary systematically as a function of firm size.
